| 16. ABSTRACT<br><p>In this study, we perform a nonlinear finite element analysis (FEA) for a circular foundation in an undrained clay under combined loading of a torque and a lateral load. To determine collapse loads, the displacement-controlled swipe loading path method is employed in FEA. Analysis results are presented in the form of failure envelopes as a function of embedment depth ratio for various definitions of ultimate lateral capacity. Results from FEA clearly show that lateral capacity is reduced by the concurrent application of torsion, and the reduction effects are quantified as a function of torque-to-lateral load ratio.</p> <p>Based on the insights gained from FEA, we further develop a novel analysis model through analytical approach. Governing differential equations for a circular foundation, embedded in a layered soil, subjected to a combination of lateral and torsional loads are derived based on energy principles and variational calculus; a total of six, interdependent differential equations are obtained. We develop a numerical algorithm to solve the interdependent differential equations and test the algorithm under individual loading components, which shows excellent agreements with those from previous studies and FEA. A full implementation of the solution algorithm for combined loading case can be done as a future study. Furthermore, the analysis model developed in this study can be regarded as a groundwork for more advanced models such as nonlinear analysis model that considers degradation of soil modulus using a piecewise-linear approach.</p> |   |  |           |

## Executive Summary

This study numerically investigates the effect of combined torsional and lateral loading on the response of circular foundations. The research team performs a series of nonlinear finite element analysis (FEA) to determine collapse loads of drilled shafts in an undrained clay using the displacement-controlled swipe loading path method. As a validation of the finite element model, we compare the results from FEA under each individual component of load (i.e., a pure torque and a pure lateral load) against previous studies and theoretical values, which shows an excellent agreement. We further present the analysis results under combined lateral and torsional loading in the form of failure envelopes with various embedment depth ratios of foundations. Results from FEA clearly show that the lateral capacity of foundations is reduced by the concurrent application of torsion. We quantify such reduction effects as a function of torque-to-lateral load ratio and present the results in the form of design charts.

Based on the insights gained from FEA, we further develop a novel analysis model through analytical approach. With an assumption of linear elasticity, we derive governing differential equations for a circular foundation, embedded in a multilayered soil, subjected to a combination of lateral and torsional loads using energy principles and variational calculus. A total of six interdependent differential equations result from the derivation. To solve the interdependent differential equations, we develop a numerical algorithm using an iterative solution scheme and test the algorithm under each individual loading component. The results from our analysis model under individual loading components show very good agreements with those from previous studies and FEA. The solution algorithm developed in this study can be fully implemented for combined loading case and thorough benchmark runs can be performed as future studies. Furthermore, the analysis model developed in this study can be regarded as the groundwork for more advanced models such as nonlinear analysis model that considers degradation of soil modulus using a piecewise-linear approach. Because the new analysis model is applicable for a multilayered soil, a systematic parametric study can be also performed to investigate the soil layering effect and optimize foundation design.

# CHAPTER 1. INTRODUCTION

## 1.1 PROBLEM STATEMENT

The three most important forces that need to be considered for design of transportation infrastructure are compression, tension, and shear. For cantilever mast-arm structures – such as sign trusses, traffic signals, and mast-arm light poles — subjected to high wind loads, torsion is a particular concern in addition to the three primary forces. Also, any transportation structure which is laterally loaded is prone to undergo some degree of torsion due to eccentricity of the applied load.

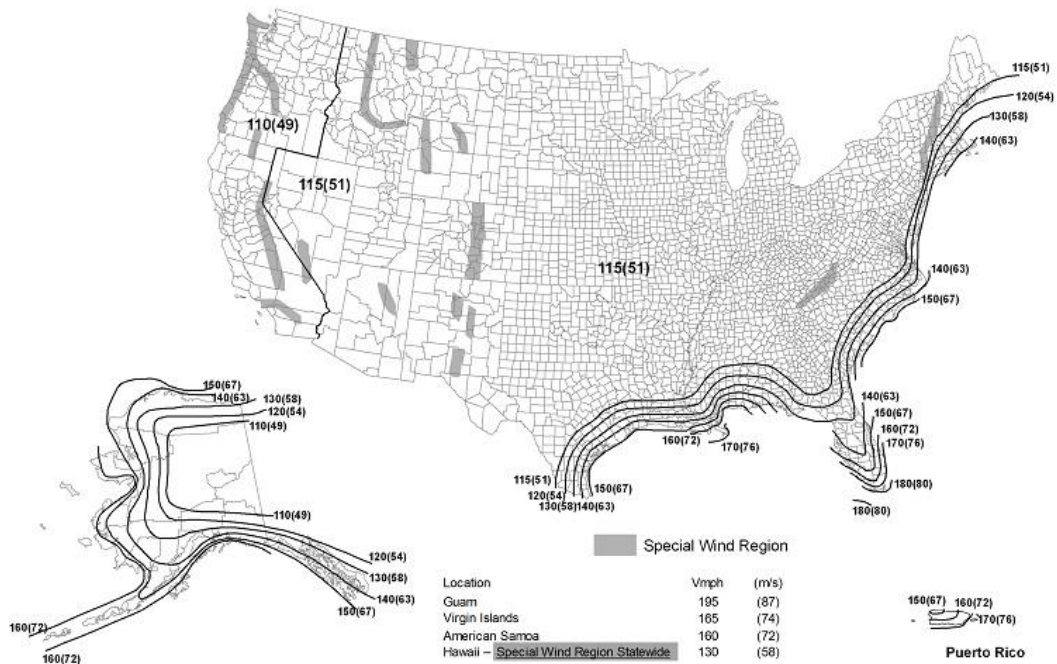

While there are considerable studies on torsional behavior of the structural elements of a superstructure, little attention has been paid to torsional behavior of a foundation surrounded by soil or rock. Most studies on behavior of foundations have focused on axial or lateral loading condition, and routine foundation design does not consider torsional behavior. Although there is a growing literature on the torsional behavior of foundations, these studies have focused on foundations subjected to pure torsion (Randolph 1981; Hache and Valsangkar 1988; Guo and Randolph 1996; Guo et al. 2007; Zhang 2010; Misra et al 2014; Li et al. 2017). However, the cantilever mast-arm structures are likely to impose a simultaneous loading of a torque and a lateral load on foundation due to their inverted L shapes. It has been reported that evaluating foundation stability against torsional and lateral load failures *separately* is not a safe practice (McVay et al. 2003). Unfortunately, no analysis models or design guidelines are available that can consider the combined effects of torsional and lateral loads on a foundation. Even, finite element analysis studies on foundations subjected to combined torsional and lateral loads are exceedingly rare.

In this study, we perform a nonlinear finite element analysis (FEA) for a circular foundation under combined loading of a torque and a lateral load. To determine collapse loads, the displacement-controlled swipe loading path method is employed. Analysis results are presented in the form of failure envelopes as a function of embedment depth ratio for various definitions of ultimate lateral capacity. Results from

FEA clearly show that lateral capacity is reduced by the concurrent application of torsion, and the reduction effects are quantified as a function of torque-to-lateral load ratio. We also derive governing differential equations for a circular foundation, embedded in a layered soil, subjected to a combination of torsional and lateral loads based on energy principles and variational calculus. We further develop a numerical algorithm to solve these differential equations and test the algorithm under individual loading components. A full implementation of the solution algorithm can lead to a development of a novel analysis model for load-displacement response of circular foundations under simultaneous action of a torque and a lateral load as a future study.

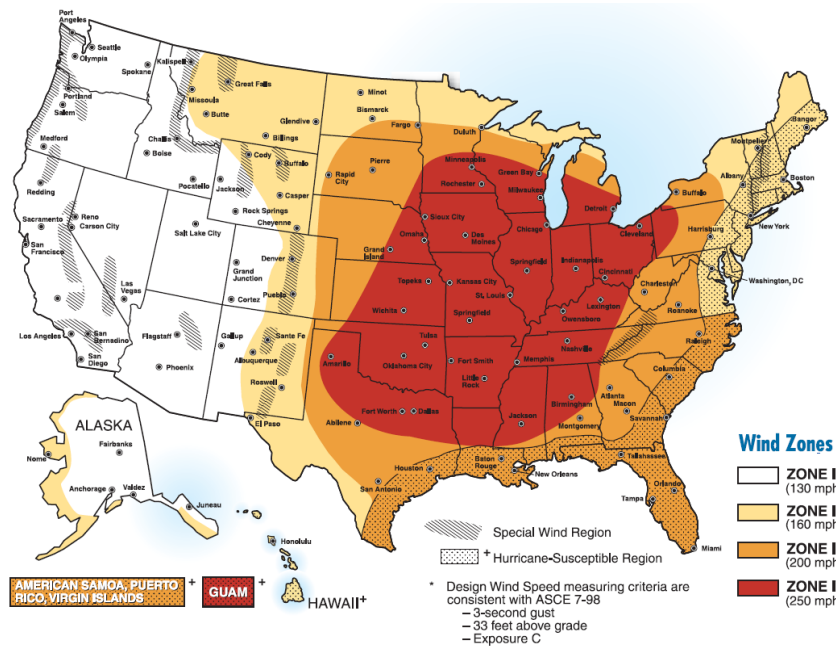

## 1.2 Background

Impact of wind loads on stability of infrastructure is a very important design consideration. According to International Building Code (IBC 2015) and Minimum Design Loads for Buildings and Other Structures: ASCE/SEI 7-10 (ASCE 2013), ultimate design wind speeds of 115 miles per hour (185 km per hour) are typical in Region 6 states (AR, LA, NM, OK, and TX) for common transportation infrastructures such as bridges, as shown in Figure 1.1(a). Figure 1.1(a) further shows that the ultimate design wind speeds along coastal areas in Louisiana and Texas are much greater than 115 mph (185 km per hour) due to hurricanes, and can be as high as 170 mph (274 km per hour). Many of the Region 6 states frequently experience tornadoes, and special structures must be designed to withstand very high wind speeds due to tornadoes. For example, FEMA (2007) recommends the wind speeds of at least 200 miles per hour (322 km per hour) in most areas of Region 6 states, except for New Mexico, for design of community tornado shelters [refer to Figure 1.1(b)].

- Notes:
1. Values are nominal design 3-second gust wind speeds in miles per hour (m/s) at 33 ft (10m) above ground for Exposure C category.
  2. Linear interpolation between contours is permitted.
  3. Islands and coastal areas outside the last contour shall use the last wind speed contour of the coastal area.
  4. Mountainous terrain, gorges, ocean promontories, and special wind regions shall be examined for unusual wind conditions.
  5. Wind speeds correspond to approximately a 7% probability of exceedance in 50 years (Annual Exceedance Probability = 0.00143, MRI = 700 Years).

(a)

(b)

Figure 1.1 (a) Ultimate design wind speeds for Risk Category II buildings and other structures (IBC 2015) and (b) Design wind speeds for community shelters (FEMA 2007)

Large lateral loads induced by high winds will impose additional compression, tension, or shear forces on structural members and should be properly considered in design. Although these forces are the most common ones for typical structures, cantilever mast-arm structures (i.e., inverted L shape structures) and structures subjected to eccentric lateral load may develop significant torsional load on foundations in addition to these forces. Figure 1.2(a) shows a foundation of a cantilever overhead sign support structure subjected to the torsional and lateral loads simultaneously, and Figure 1.2(b) shows a failure of cantilever sign support structure along I-65 in Tennessee, allegedly caused by a “prolonged exposure to wind created by tractor trailer gusts (Beneberu et al. 2014).”

(a)

(b)

Figure 1.2 (a) A foundation of cantilever overhead sign support subjected to the torsional and lateral loads simultaneously and (b) failure of cantilever sign support structure along I-65 in Tennessee (Beneberu et al. 2014)

As mentioned previously, when the torsional loads are considered, the current geotechnical design practice is to evaluate stability of foundations against torsional and lateral load failures separately. The effects of a torque on lateral capacity of foundation (or vice versa) are barely understood. However, recent centrifuge tests and field tests performed by the researchers at University of Florida (McVay et al. 2003; Hu et al. 2006; Thiyyakkandi et al. 2016) have suggested that the lateral capacity of a drilled shaft is reduced when a torque and a lateral load are concurrently applied. This indicates that the current practice of separate evaluation of foundation stability against torsional and lateral load failures is not a safe practice. Because performing full-scale tests for various soil conditions with a wide range of foundation dimensions is practically and economically not feasible, there is a strong need to quantify the combined effects of lateral and torsional loads on foundation capacity through numerical analysis.

### 1.3 Objectives

The goal of this study is to numerically investigate the torsional and lateral resistances of circular foundations under combined loading. The main objectives of the study include:

- (a) Performing nonlinear finite element analysis to determine failure envelopes under combined torsional and lateral loading
- (b) Quantifying the effect of a torque on lateral capacity for various torque-to-lateral load ratios
- (c) Deriving governing differential equations for load-displacement response of a circular foundation in a layered soil subjected to torsional and lateral loads
- (d) Developing solution algorithm to solve the differential equations numerically.

## CHAPTER 2. NUMERICAL MODELLING

### 2.1 Finite element model

The finite element analysis (FEA) is employed to investigate the behavior of a circular foundation subjected to under combined torsional and lateral loading using ABAQUS version 6.16 (Dassault Systèmes, 2016). The circular foundation, represented by a drilled shaft in this study, has a diameter  $D$  and a length  $L_p$ , embedded in a homogenous clay layer under undrained conditions. The diameter of the drilled shaft is set to be 1 m, and the effect of the embedment depth is investigated with three different lengths of the drilled shaft ( $L_p = 3, 5, \text{ and } 10$  m, corresponding to embedment depth ratios  $L_p/D$  of 3, 5, and 7, respectively). The  $L_p/D$  was limited to 10 because the embedment depth ratios of foundations for mast arm traffic sign and signal pole structures typically are smaller than 10. The linear elastic-perfectly plastic Tresca failure criterion is used to describe the clay behavior with an undrain shear strength of  $s_u$  and an undrained Young's modulus of  $E_u = 500s_u$ . To simulate the constant volume response during undrained loading, a Poisson's ratio  $\nu_s$  of 0.49 was used for the clay along with zero degree of friction and dilation angles. The drilled shaft is modelled as a linear elastic material with a Young's modulus  $E_p = 25$  GPa and Poisson's ratio  $\nu_p = 0.3$ .

Eight-node brick elements with reduced integration (C3D8R) were used to model the drilled shaft and surrounding soil. A thin band of soil elements was used to capture the severe distortion close to the foundation without an interface model, as has been done by other researchers (Taiebat and Carter 2004 and Fan and Meng 2011). The domain boundaries are  $30D$  (*i.e.*, 30 times the foundation diameter) in the horizontal direction and  $2L_p$  (*i.e.*, 2 times the foundation length) in the vertical direction to minimize the boundary effect. The side boundary is horizontally fixed, and the base boundary is fixed in both horizontal and vertical directions. Analyses were performed under displacement-controlled conditions, where lateral and torsional displacements were applied at the foundation head and gradually increased.

## 2.2 Analysis results under a pure lateral load or a pure torque

The response of the drilled shaft under each individual component of load is presented first, followed by that under the combined loading.

### 2.2.1 Lateral response

The ultimate lateral capacity of a short foundation in an undrained clay can be obtained as follows:

$$H_{\max} = N_h L_p D s_u \quad (2.1)$$

where  $H_{\max}$  = ultimate lateral capacity,  $L_p$  = foundation embedment depth,  $D$  = foundation diameter,  $s_u$  = undrained shear strength of clay, and  $N_h$  = lateral capacity factor. Deng and Carter (1999) suggested that  $N_h = 4.8$  for a caisson with load applied at the foundation head, which is also a ground surface.

The load-displacement ( $H-w_r$ ) responses of the drilled shafts obtained from FEA under lateral load with  $L_p = 3, 5,$  and  $10$  m are presented in Figures 2.1(a), (b), and (c), respectively.

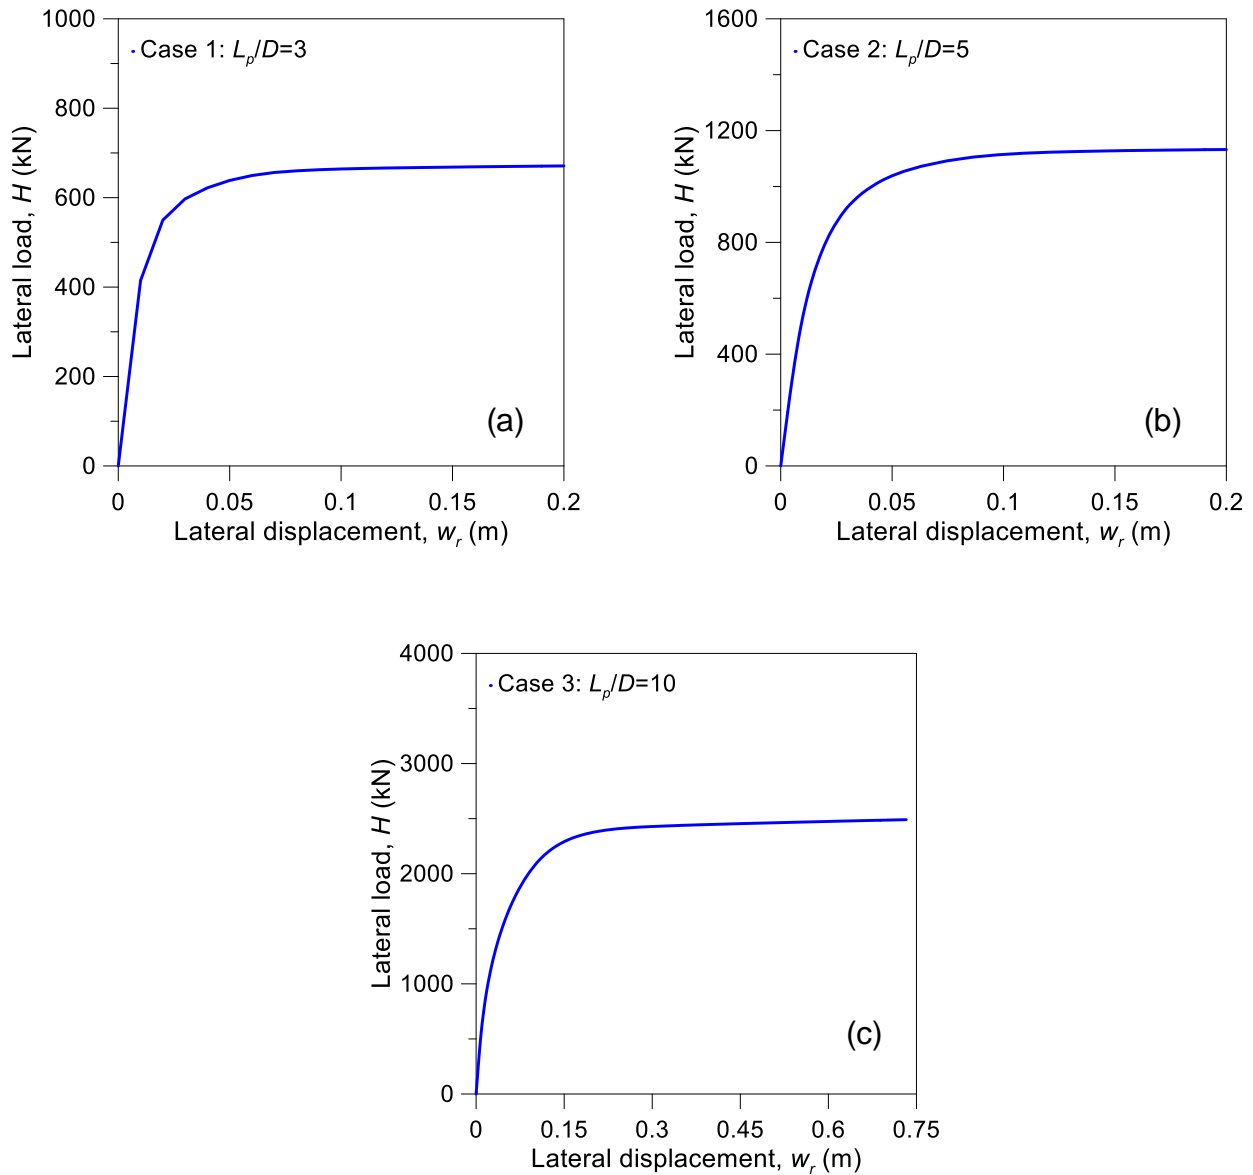

Figure 2.1 Load-displacement response under pure lateral loading: (a)  $L_p/D = 3$ , (b)  $L_p/D = 5$ , and (c)  $L_p/D = 10$

The responses of drilled shafts under pure lateral load show nonlinear behavior, and it is clear that the lateral load approaches an asymptotic value at a large displacement. Although there are many criteria available in literature for determination of ultimate capacity of foundations under axial loading, such criteria are not well established for laterally loaded foundations. With the absence of widely accepted criteria for determination of ultimate lateral capacity  $H_{max}$ , we use four different ultimate capacity criteria in this study:

- 1)  $H_{max}$  is defined as a load  $H_{ult}$  after which the increase between two successive loads becomes less than 0.1%; this load is very close to the asymptotic value and might be considered as a true failure load;
- 2)  $H_{max}$  is defined as a load  $H_{0.1D}$  at a lateral displacement corresponding to 10% of foundation diameter ( $w_{r,ult} = 0.1D$ );
- 3)  $H_{max}$  is defined as a load  $H_{0.05D}$  at a lateral displacement corresponding to 5% of foundation diameter ( $w_{r,ult} = 0.05D$ );
- 4)  $H_{max}$  is defined as a load  $H_{0.025D}$  at a lateral displacement corresponding to 2.5% of foundation diameter ( $w_{r,ult} = 0.025D$ ).

Graphical illustrations of each criterion are presented in Figure 2.2.

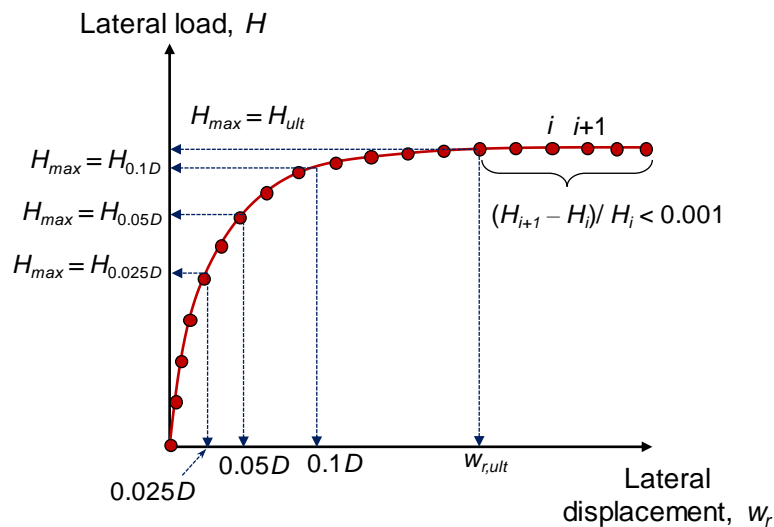

Figure 2.2 Graphical illustrations of ultimate lateral capacity criteria used in this study

Ultimate lateral capacities  $H_{max}$  determined using the aforementioned four criteria and their corresponding lateral displacements  $w_{r,ult}$  are summarized in Table 2.1.

Table 2.1 Summary of ultimate lateral capacities under pure lateral loading for various ultimate capacity criteria

| $L_p/D$ | $H_{\max} = H_{ult}$<br>(kN) | $w_{r,ult}$<br>(m) | $N_h$ | $H_{\max} = H_{0.1D}$<br>(kN) | $w_{r,ult}$<br>(m) | $H_{\max} = H_{0.05D}$<br>(kN) | $w_{r,ult}$<br>(m) | $H_{\max} = H_{0.025D}$<br>(kN) | $w_{r,ult}$<br>(m) |
|---------|------------------------------|--------------------|-------|-------------------------------|--------------------|--------------------------------|--------------------|---------------------------------|--------------------|
| 3       | 668                          | 0.15               | 4.45  | 664                           | 0.1                | 636                            | 0.05               | 574                             | 0.025              |
| 5       | 1130                         | 0.18               | 4.52  | 1115                          | 0.1                | 1038                           | 0.05               | 871                             | 0.025              |
| 10      | 2478                         | 0.63               | 4.96  | 2078                          | 0.1                | 1591                           | 0.05               | 1136                            | 0.025              |

Lateral capacity factors  $N_h$  from FEA were determined to be 4.45, 4.52, and 4.96 for foundations with  $L_p/D = 3, 5,$  and  $10,$  respectively, using  $H_{\max} = H_{ult},$  and their values are given in Table 2.1. Despite slight differences, these lateral capacity factors are overall in good agreement with  $N_h = 4.8$  obtained by Deng and Carter (1999) from their numerical analyses.

### 2.2.2 Torsional response

The relationship between a torque and an angle of twist for a straight cylinder with a fixed end is given as follows from elasticity theory:

$$\psi_p = \frac{TL_p}{G_p J_p} \quad (2.2)$$

where  $\psi_p =$  angle of twist,  $T =$  applied torque,  $G_p =$  shear modulus of the cylinder, and  $J_p =$  polar moment of inertia of cross section of the cylinder (see Figure 2.3).

Figure 2.3 Angle of twist of a cylinder subjected to a torque

As shown in Figure 2.3, the angle of twist is greatest at the top of the cylinder and becomes zero at the base due to the fixed end condition. However, for a foundation embedded in soil, the angle of twist at the foundation base is not necessarily zero, especially for short foundations. Furthermore, when a torque is applied at the foundation head, frictional resistances develop 1) between the foundation and the surrounding soil along the shaft and 2) between the foundation base and the soil beneath it (refer to Figure 2.4). Therefore, an ultimate torsional capacity of a foundation in a homogeneous soil with an undrained shear strength  $s_u$  can be calculated as the sum of the shaft and base resistances as follows:

$$T_{\max} = T_s + T_b = (s_u \pi D L_p) \left( \frac{D}{2} \right) + \int_0^{D/2} (s_u) (2\pi r) dr = s_u \pi D^2 \left( \frac{L_p}{2} + \frac{D}{12} \right) \quad (2.3)$$

where  $T_{\max}$  = ultimate torsional capacity.

Figure 2.4 Torsional resistances of the foundation in soil

The torque-angle of twist ( $T-\psi_p$ ) responses of the drilled shafts obtained from FEA under a pure torque with  $L_p = 3, 5,$  and  $10$  m are presented in Figures 2.5(a), (b), and (c), respectively. The torsional resistance from FEA linearly increases to its ultimate value and then remains constant after that, showing a behavior that is very close to linear-elastic, perfectly-plastic. Ultimate torsional capacity  $T_{max}$  and the corresponding angle of twist  $\psi_{p,ult}$  from FEA were taken to be the values where a sudden change in slope was observed from the  $T-\psi_p$  plots. For comparison purposes,  $T-\psi_p$  responses from Eqs. (2.2) and (2.3) are also plotted in Figure 2.5, assuming that the angle of twist linearly increases until  $T$  reaches  $T_{max}$  and remain constants thereafter. Values of  $T_{max}$  and  $\psi_{p,ult}$  obtained from the FEA and elasticity theory are summarized in Table 2.2

Figure 2.5 Torque-angle of twist response under pure torsional loading: (a)  $L_p/D = 3$ , (b)  $L_p/D = 5$ , and (c)  $L_p/D = 10$

\* [6] =  $\{[4]-[2]\}/[4] \times 100\%$

Figure 2.5 and Table 2.2 show that  $T_{max}$  values from FEA and Eq. (2.3) are in excellent agreements, with the largest difference being only 0.9% for Case 3 ( $L_p/D = 10$ ).

However, the angle of twist  $\psi_{p,ult}$  at the onset of the ultimate state show some discrepancies. For Cases 1 and 2 ( $L_p/D = 3$  and 5, respectively),  $\psi_{p,ult}$  values at the foundation head from Eq. (2.2) are smaller than those from FEA. On the contrary,  $\psi_{p,ult}$  from Eq. (2.2) is greater than that from FEA for Case 3. This is because Eq. (2.2) assumes the full fixity condition at the cylinder base (i.e.,  $\psi_p$  at the cylinder base is zero) but, in case of foundations, the foundation base is not fully fixed and the angle of twist at the foundation head is a summation of the rotation at the foundation base and angle of twist along the foundation shaft. As shown in Figure 2.6, the amount of angle of twist along the foundation shaft (i.e., the difference in  $\psi_p$  between the foundation head and base) is smaller than the values computed from Eq. (2.2) for all three cases because of resistances offered by the surrounding soil. However, foundation base undergoes certain levels of rotation as well and, consequently, the angle of twist at the foundation head depends on the amount of rotation at the foundation base, which is in turn influenced by the foundation embedment depth ratio. Figure 2.6, in conjunction with Figure 2.5 and Table 2.2, supports that the results from FEA well conform to the physics of the problem.

Figure 2.6 Angle of twist versus depth under pure torsional loading: (a)  $L_p/D = 3$ , (b)  $L_p/D = 5$ , and (c)  $L_p/D = 10$

## 2.3 Analysis results under combined lateral and torsional loading

### 2.3.1 Numerical loading method

To determine the failure envelope under combined torsional and lateral loads, a two-staged, displacement-controlled swipe loading method, proposed by Tan (1990), was employed in our FEA. In the first stage, a lateral displacement  $w_r$  of the drilled shaft is prescribed and incrementally increased until the drilled shaft reaches an ultimate lateral load  $H_{max}$ . Once the ultimate lateral load and its corresponding lateral displacement  $w_{r,ult}$  are determined, then an angle of twist  $\psi_p$  of the drilled shaft head is gradually increased in the second stage while keeping the lateral displacement constant at  $w_{r,ult}$ . The loading locus during the second stage can be considered as the failure envelope on the lateral-torsional load space. The displacement-controlled swipe loading method have been widely used to determine failure envelopes for isolated footings under various combined loading spaces (Gourvenec and Randolph, 2003; Vulpe et al., 2014; Lee et al 2016).

### 2.3.2 Failure envelopes under combined lateral and torsional loading

A series of finite element analyses was performed to obtain failure envelopes of the drilled shafts subjected to a combination of lateral and torsional loading, and they are

presented in

Figure 2.7. Note that four different definitions of  $H_{max}$  (i.e.,  $H_{max} = H_{ult}$ ,  $H_{0.1D}$ ,  $H_{0.05D}$ , and  $H_{0.025D}$ ), as presented in Figure 2.2 and Table 2.1, were used to plot the failure envelopes. Accordingly, a lateral displacement was gradually increased until reaching  $w_{r,ult}$  for each definition of  $H_{max}$ , and then an angle of twist  $\psi_p$  of the drilled shaft was increased while keeping the lateral displacement constant at  $w_{r,ult}$ .

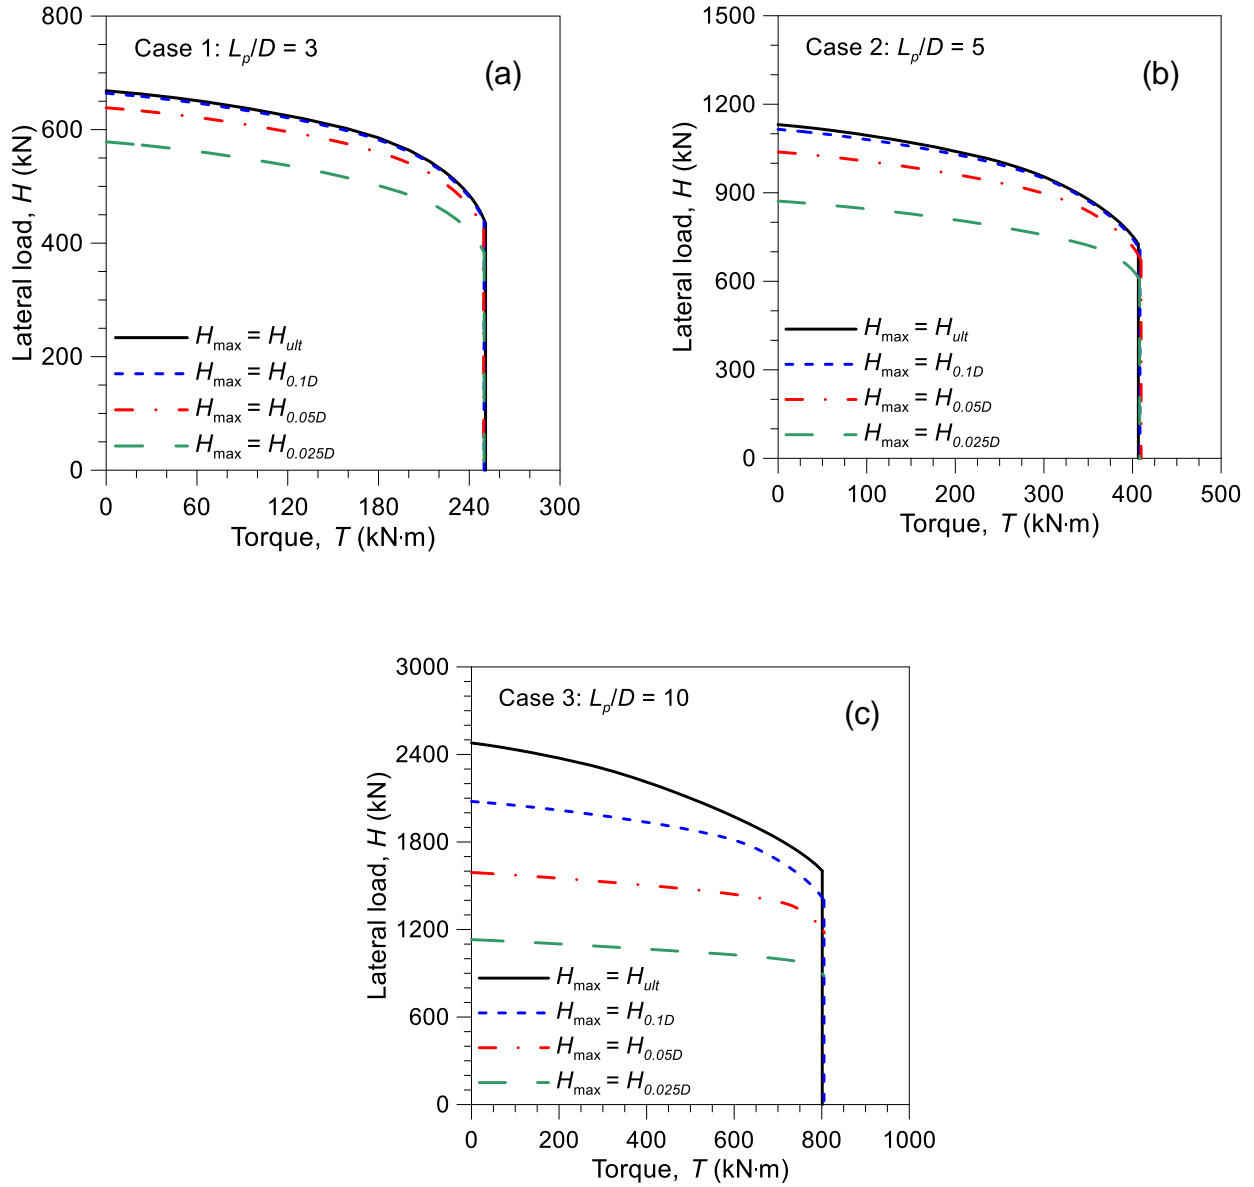

Figure 2.7 Failure envelopes in a lateral-torsional loading plane: (a)  $L_p/D = 3$ , (b)  $L_p/D = 5$ , and (c)  $L_p/D = 10$

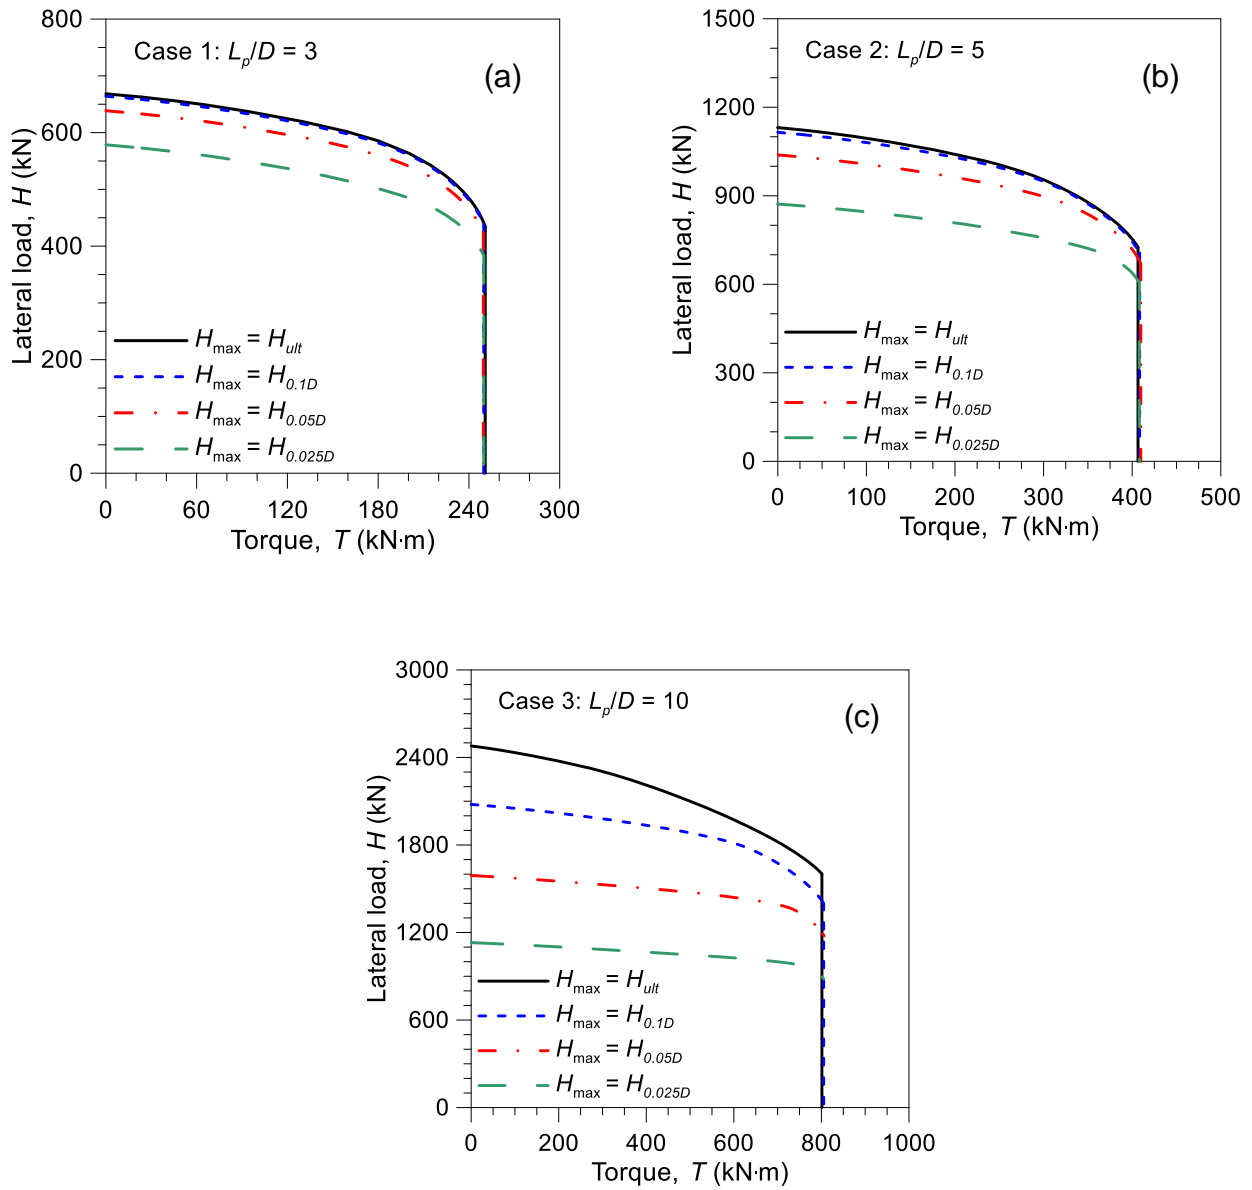

Figure 2.7 suggests that lateral loads at each failure envelope (i.e., equivalent to the maximum lateral capacity for each ultimate capacity criteria) decreases with an

increasing torsional load. The lateral and torsional loads shown in

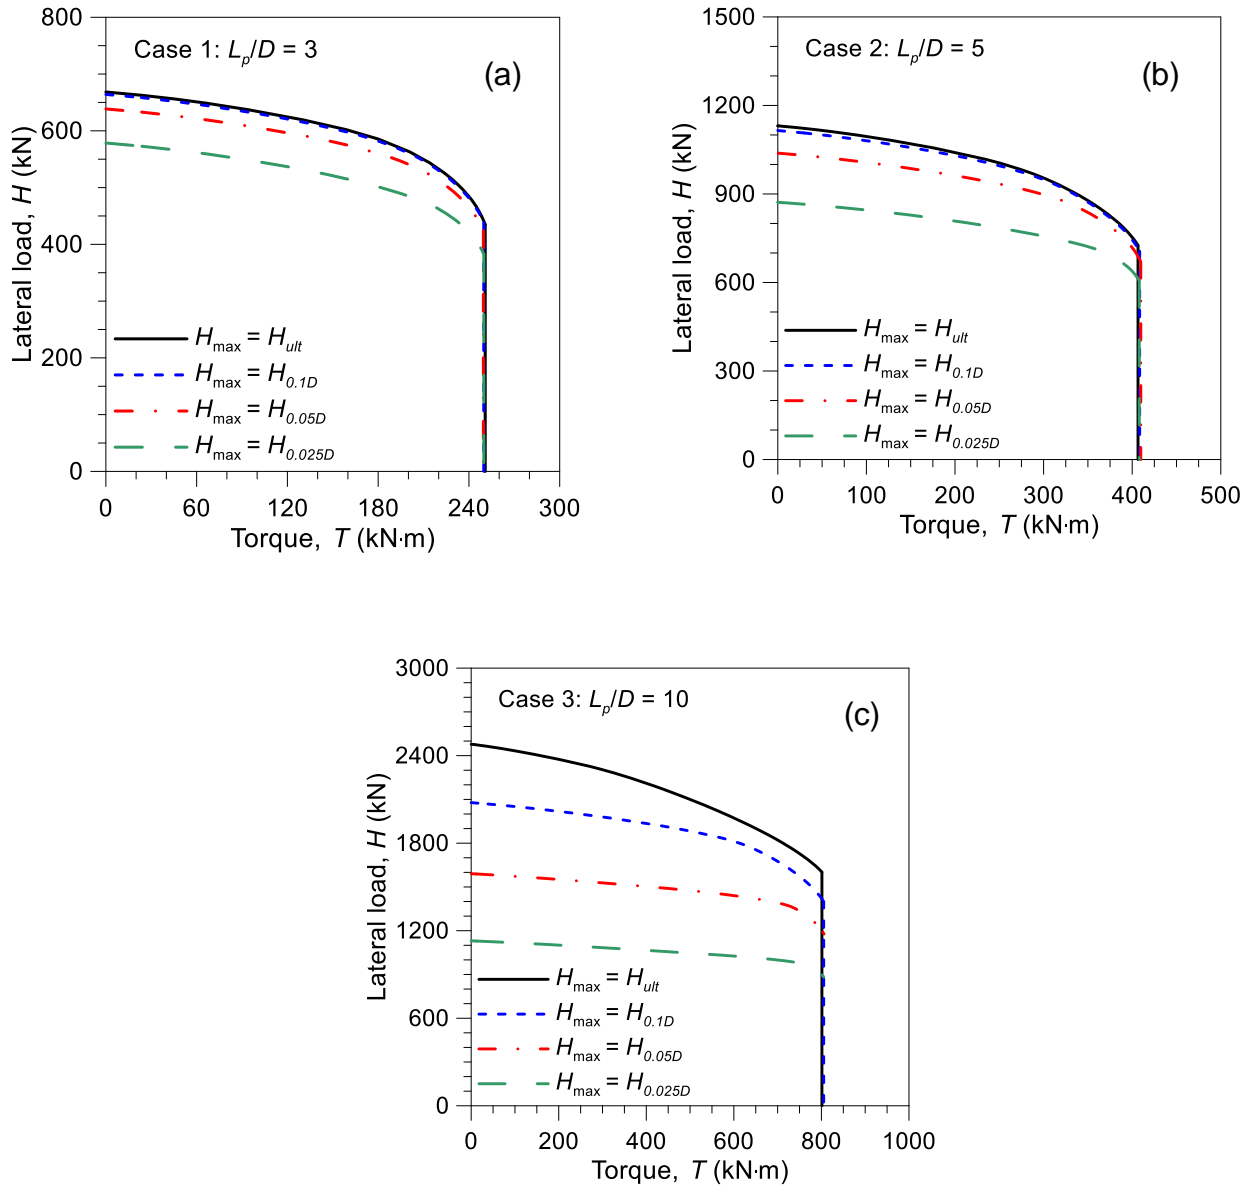

Figure 2.7 are normalized with respect to their maximum values  $H_{max}$  and  $T_{max}$  obtained under a pure lateral load and a pure torque, respectively, and the normalized failure envelopes are presented in Figure 2.8.

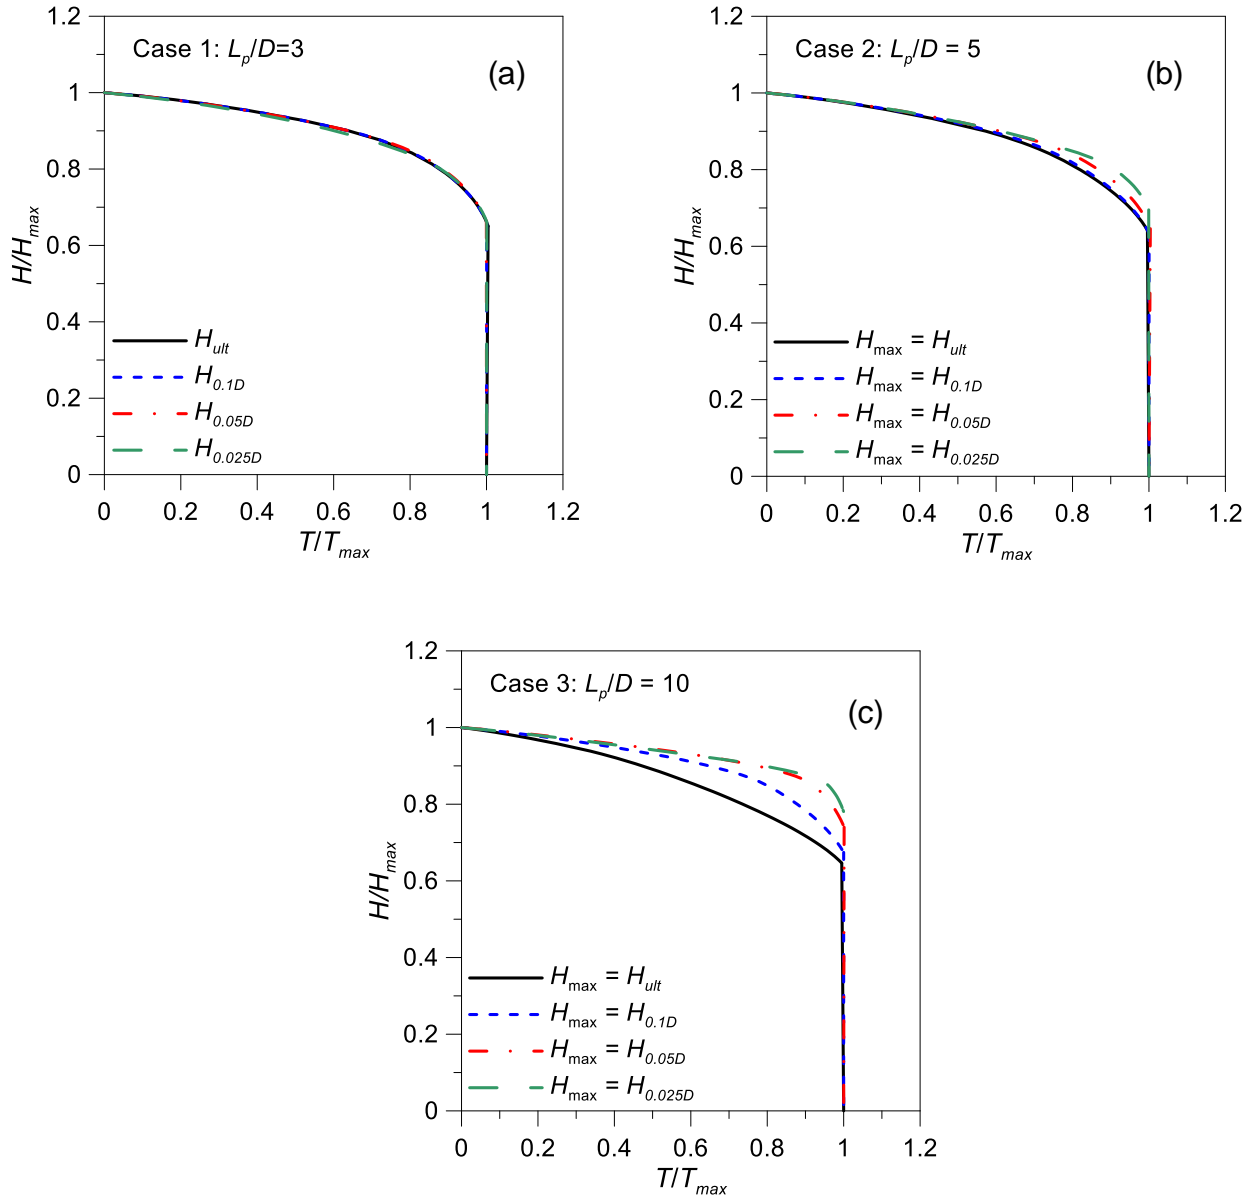

Figure 2.8 Failure envelopes in a lateral-torsional loading plane normalized with respect to  $H_{max}$  and  $T_{max}$ : (a)  $L_p/D = 3$ , (b)  $L_p/D = 5$ , and (c)  $L_p/D = 10$

For  $L_p/D = 3$ , the normalized failure envelopes fall on top of each other regardless of definitions of  $H_{max}$ ; this suggests that a single failure envelope may be used for a foundation with an embedment depth ratio less than 3. However, as the embedment depth ratio  $L_p/D$  increases, the normalized failure envelopes deviate from each other and do not justify the use of single failure envelope. Nonetheless, Figure 2.8 clearly

suggest that the lateral capacity decreases as the torsional load increases, and vice versa, regardless of how ultimate capacity is defined.

What could be more useful for design purpose is a chart that shows how much lateral capacity needs to be reduced for a given torque-to-lateral load ratio  $T/H$ . To achieve this,  $H/H_{max}$  versus  $T/H$  are plotted in Figure 2.9 using the torsional and lateral loads presented in

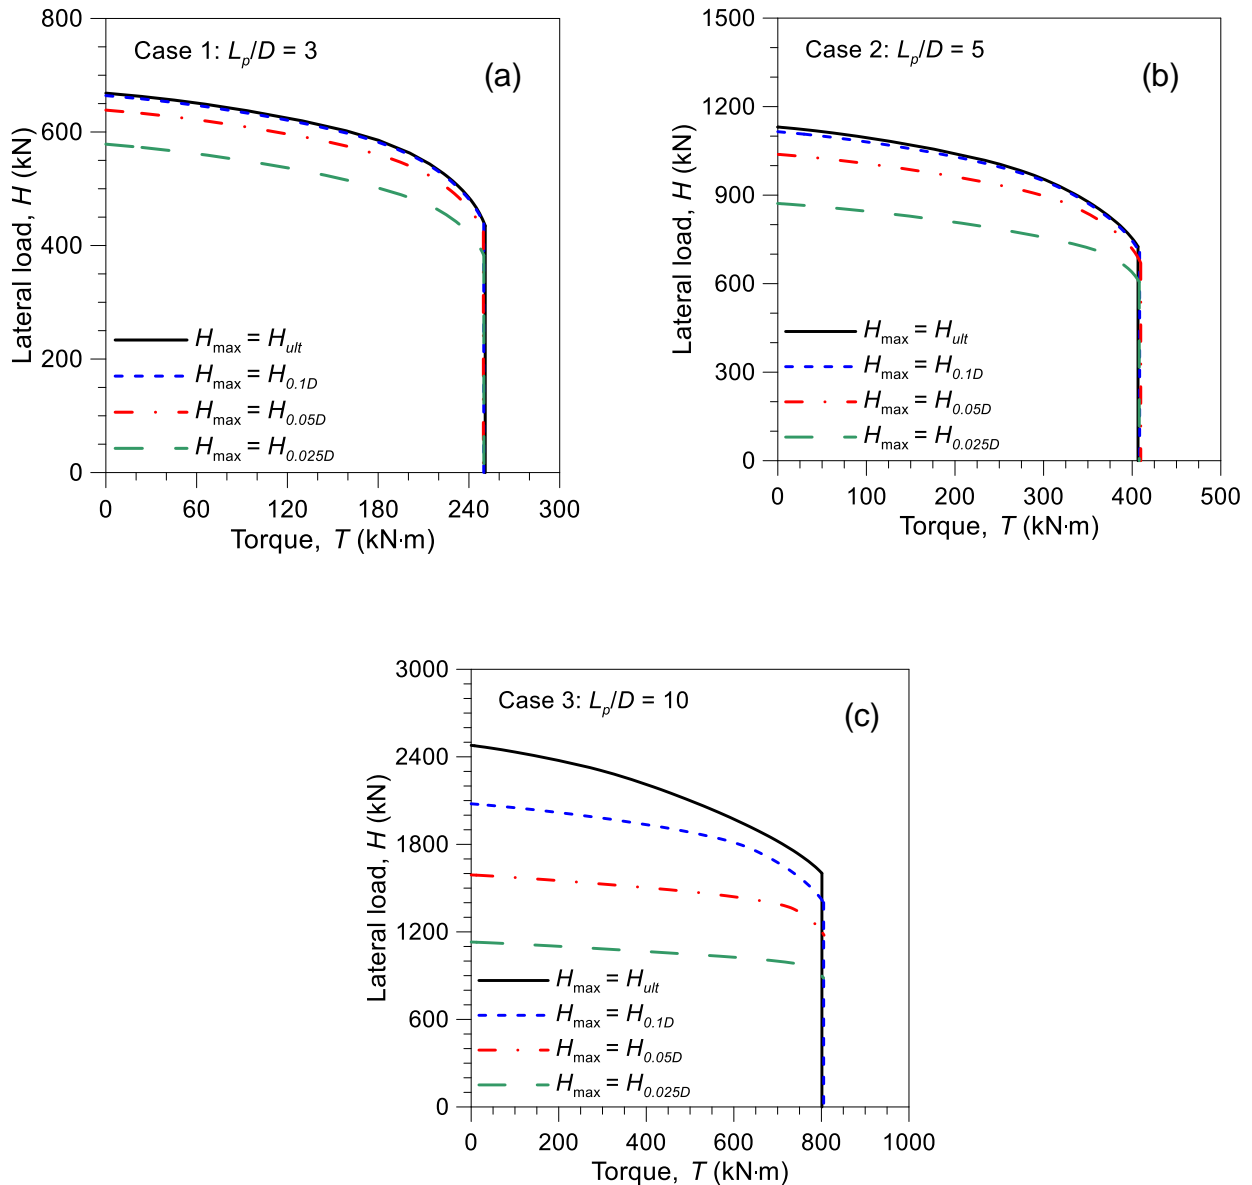

Figure 2.7. To illustrate how the charts in Figure 2.9 can be used for design, let us assume that the ultimate capacity criterion for lateral loading is defined as a load corresponding to a foundation head deflection of 10% of foundation diameter ( $H_{\max} = H_{0.1D}$ ). In the absence of a torsional loading ( $T/H = 0$ ), 100% of  $H_{\max}$  can be used as an ultimate lateral capacity. However, if the foundation is to be subjected to a simultaneous loading of a torque and a lateral load with a ratio  $T/H$  of 0.5 m (say,  $T = 250$  kN-m and  $H = 500$  kN), then the charts Figure 2.9 suggest that the full lateral capacity cannot be used and should be reduced to 70~73% of  $H_{\max}$ . Similarly, for the ultimate capacity criterion of  $H_{\max} = H_{0.025D}$ , the lateral capacity needs to be reduced to 79~92% of  $H_{\max}$  for  $T/H = 0.5$  m, depending on  $L_p/D$ . The greatest reduction of lateral capacity observed from the FEA was about 63% with a  $T/H$  of 0.58 m for  $L_p/D = 5$  (refer to Figure 2.9b). Whether  $H/H_{\max}$  continues to decrease beyond the range of  $T/H$  considered in this study is unknown at this time and warrants further investigation. Typical ranges of  $T/H$  for various transportation infrastructures will also need to be examined in future studies.

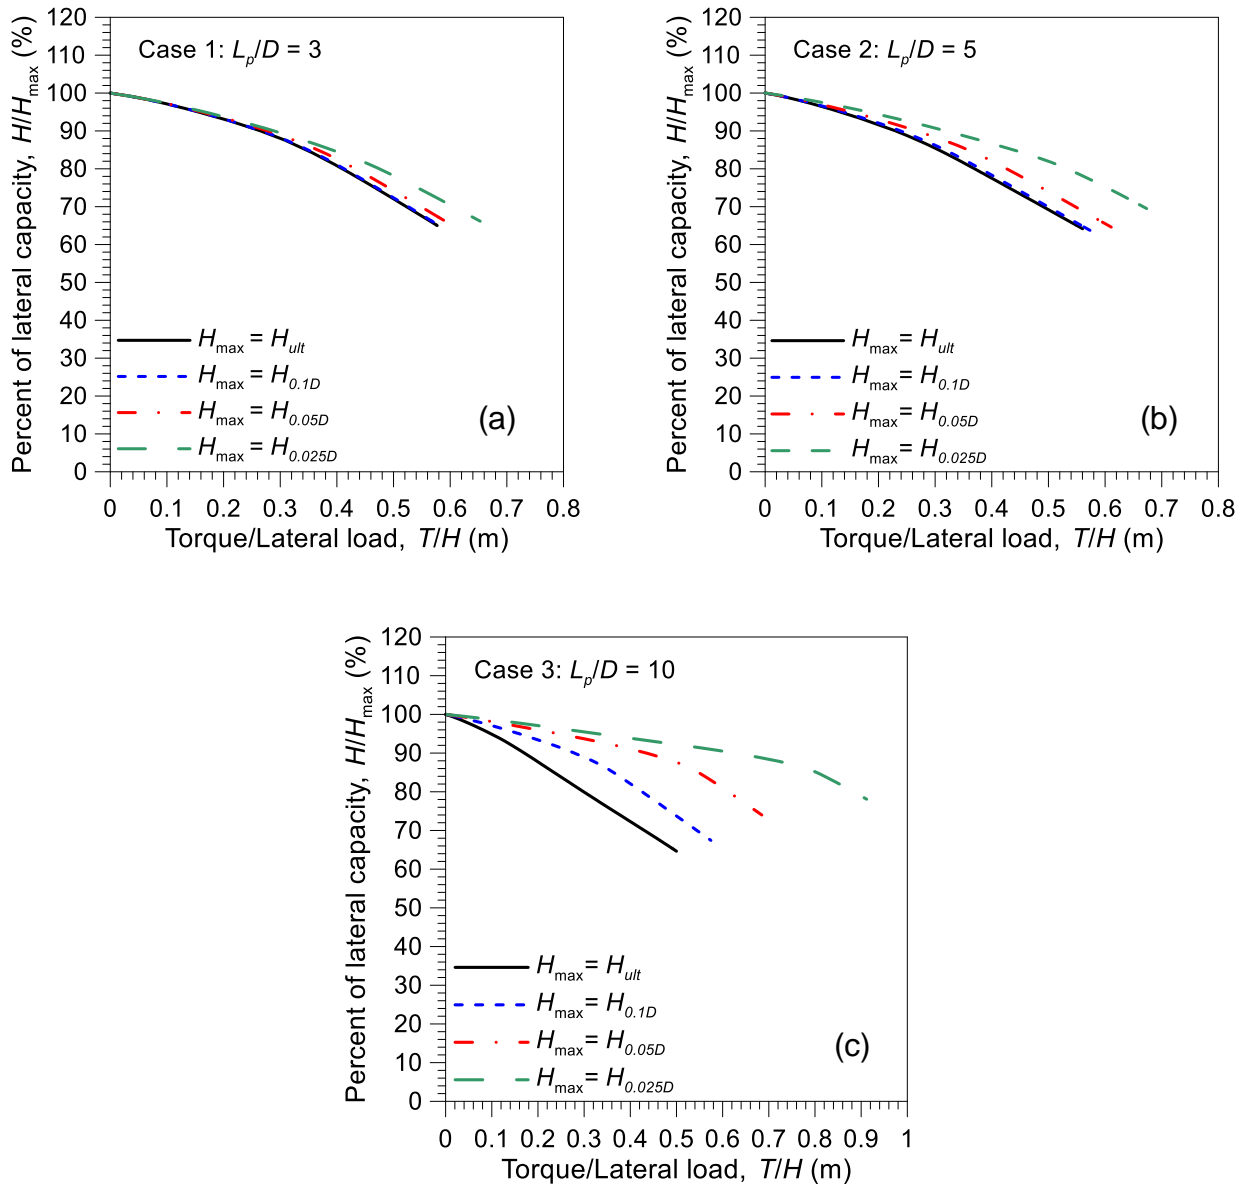

Figure 2.9 Lateral capacity reduction versus torque-to-lateral load ratio: (a)  $L_p/D = 3$ , (b)  $L_p/D = 5$ , and (c)  $L_p/D = 10$

### 2.3.3 Failure mechanisms

To observe failure mechanisms of foundations subjected to combined lateral and torsional loads, the contour plots of maximum principal plastic strains obtained for the drilled shaft with  $L_p/D = 3$  are presented, as a representative case, in Figure 2.10 for

various loading levels. The plastic zone is very small at lower loading levels but becomes greater as the lateral load increases. When an ultimate lateral load is applied, much higher levels of plastic strains are observed near the foundation head and base than the middle portion of the foundation (refer to the figure at  $H_{ult}$  in Figure 2.10a). Upon additional torsional loading, the plastic zone propagates along the foundation and the entire shaft is subjected to high plastic strain levels (refer to the figure at  $H_{ult} - T_{ult}$  in Figure 2.10a). Furthermore, the thickness of plastic zone becomes greater when the foundation is subjected an additional torsional loading (see the figure at  $H_{ult} - T_{ult}$  in Figure 2.10b).

## CHAPTER 3. ANALYTICAL MODELLING

### 3.1 Introduction

As seen in CHAPTER 2, FEA successfully captures the effect of combined loading of a torque and a lateral on the behavior of circular foundations. However, it requires extensive computational efforts to determine failure envelopes and is often beyond the reach of ordinary engineers who may not be well versed in FEA. This chapter presents our efforts to develop an easy-to-use-yet-mathematically-rigorous analysis tool through analytical modelling of a circular foundation subjected to concurrent application of lateral and torsional loads.

### 3.2 Mathematical formulation

#### 3.2.1 Problem definition and basic assumptions

We consider a cylindrical foundation of length  $L_p$  and circular cross section of diameter  $D (=2r_p)$ . The foundation, which is under a lateral load  $H$  and a torque  $T$ , is embedded in a total of  $N$  horizontal soil layers. The foundation itself crosses  $m$  layers, while  $N - m$  layers exist below the base of the foundation. All soil layers extend to infinity in the radial direction, and the bottom ( $N^{th}$ ) layer extends to infinity downward in the vertical direction. As shown in Figure 3.1,  $z_{H,i}$  denotes the vertical depth from the ground surface to the bottom of any layer  $i$ , which implies that the thickness of layer  $i$  is  $z_{H,i} - z_{H,i-1}$  with  $z_{H,0} = 0$  and  $z_{H,N} = \infty$ .

Figure 3.1 Geometry of the foundation-soil system

Since the problem is axisymmetric, we choose a system of cylindrical coordinates with the origin coinciding with the center of the foundation cross section at the foundation head and the  $z$  axis coinciding with the foundation axis ( $z$  is positive in the downward direction). The soil medium within each layer is assumed to be isotropic, homogeneous, and linear elastic, with elastic properties described by Lamé's constants  $\lambda_{si}$  and  $G_{si}$ , which can be related to more recognizable  $E_{si} - \nu_{si}$  pair of elastic constants:  $\lambda_{si} = E_{si}\nu_{si}/[(1+\nu_{si})(1-2\nu_{si})]$  and  $G_{si} = E_{si}/[2(1+\nu_{si})]$ . The foundation is described as a linear elastic material with Young's modulus  $E_p$  and shear modulus  $G_p$ . It is also assumed that there is no slippage or separation between the foundation and the surrounding soil or between soil layers.

### 3.2.2 Soil displacements

The soil displacement fields at any point of soil medium are assumed to be a product of separable variables, as done by many researchers (Vlasov and Leont'ev 1966; Vallabhan and Mustafa 1996; Basu et al. 2009; Seo et al. 2009; Salgado et al. 2013), as follows:

$$u_r(r, \theta, z) = [w_r(z) \cos \theta] \phi_r(r) \quad (3.1)$$

$$u_\theta(r, \theta, z) = [-w_r(z) \sin \theta + w_\theta(z)] \phi_\theta(r) = [-w_r(z) \sin \theta + r_p \psi_p(z)] \phi_\theta(r) \quad (3.2)$$

$$u_z(r, \theta, z) = 0 \quad (3.3)$$

where  $u_r(r, \theta, z)$ ,  $u_\theta(r, \theta, z)$ , and  $u_z(r, \theta, z)$  = lateral, tangential, and vertical soil displacements, respectively, at any point  $(r, \theta, z)$  in the soil mass (refer to Figure 3.1);  $w_r(z)$  = lateral displacement at the foundation-soil interface as a function of depth  $z$ ;  $w_\theta(z)$  = tangential displacement at the foundation-soil interface as a function of depth  $z$ ;  $\psi_p(z)$  = angle of twist of the foundation cross section ( $\psi_p = w_\theta/r_p$ ) varying with depth  $z$ ; and  $\phi_r(r)$  and  $\phi_\theta(r)$  = dimensionless functions varying along the radial distance  $r$ ; these  $\phi$  functions are shape functions that describe the decreases in the soil displacements with increasing radial distance from the foundation axis. The  $\phi$  functions are equal to one at the foundation-soil interface (*i.e.*, to  $r = r_p$ ), and this ensures proper foundation-soil contact. Furthermore, the  $\phi$  functions are zero at  $r = \infty$  because the soil displacements must vanish at infinite horizontal distances from the foundation. Eq. (3.2) clearly states that the tangential soil displacement is influenced not only by the tangential displacement of the foundation due to the applied torque but also by the lateral displacement of the foundation caused by the lateral load. Eq. (3.3) assumes that the vertical displacement of the soil caused by the lateral and torsional loads is negligible.

### 3.2.3 Stress-strain-displacement relationships

The stress-strain relationship in an isotropic and elastic soil medium is expressed as follows:

$$\begin{bmatrix} \sigma_{rr} \\ \sigma_{\theta\theta} \\ \sigma_{zz} \\ \tau_{r\theta} \\ \tau_{rz} \\ \tau_{\theta z} \end{bmatrix} = \begin{bmatrix} \lambda_s + 2G_s & \lambda_s & \lambda_s & 0 & 0 & 0 \\ \lambda_s & \lambda_s + 2G_s & \lambda_s & 0 & 0 & 0 \\ \lambda_s & \lambda_s & \lambda_s + 2G_s & 0 & 0 & 0 \\ 0 & 0 & 0 & G_s & 0 & 0 \\ 0 & 0 & 0 & 0 & G_s & 0 \\ 0 & 0 & 0 & 0 & 0 & G_s \end{bmatrix} \begin{bmatrix} \varepsilon_{rr} \\ \varepsilon_{\theta\theta} \\ \varepsilon_{zz} \\ \gamma_{r\theta} \\ \gamma_{rz} \\ \gamma_{\theta z} \end{bmatrix} \quad (3.4)$$

where  $\sigma_{rr}$ ,  $\sigma_{\theta\theta}$ ,  $\sigma_{zz}$  = normal stresses;  $\tau_{r\theta}$ ,  $\tau_{rz}$ ,  $\tau_{\theta z}$  = shear stresses;  $\varepsilon_{rr}$ ,  $\varepsilon_{\theta\theta}$ ,  $\varepsilon_{zz}$  = normal strains;  $\gamma_{r\theta}$ ,  $\gamma_{rz}$ ,  $\gamma_{\theta z}$  = shear strains.

With the assumed displacement field given in Eqs. (3.1) through (3.3), the strain-displacement relationship is given by:

$$\begin{bmatrix} \varepsilon_{rr} \\ \varepsilon_{\theta\theta} \\ \varepsilon_{zz} \\ \gamma_{r\theta} \\ \gamma_{rz} \\ \gamma_{\theta z} \end{bmatrix} = \begin{bmatrix} -\frac{\partial u_r}{\partial r} \\ \frac{u_r}{r} - \frac{1}{r} \frac{\partial u_\theta}{\partial \theta} \\ -\frac{\partial u_z}{\partial z} \\ -\frac{1}{r} \frac{\partial u_r}{\partial \theta} - \frac{\partial u_\theta}{\partial r} + \frac{u_\theta}{r} \\ \frac{\partial u_z}{\partial r} - \frac{\partial u_r}{\partial z} \\ -\frac{1}{r} \frac{\partial u_z}{\partial \theta} - \frac{\partial u_\theta}{\partial z} \end{bmatrix} = \begin{bmatrix} -w_r \frac{d\phi_r}{dr} \cos \theta \\ \frac{w_r \cos \theta}{r} (\phi_\theta - \phi_r) \\ 0 \\ w_r \frac{\phi_r}{r} \sin \theta + (w_r \sin \theta - r_p \psi_p) \left( \frac{d\phi_\theta}{dr} - \frac{\phi_\theta}{r} \right) \\ -\frac{dw_r}{dz} \phi_r \cos \theta \\ \left( \frac{dw_r}{dz} \sin \theta - r_p \frac{d\psi_p}{dz} \right) \phi_\theta \end{bmatrix} \quad (3.5)$$

### 3.2.4 Potential energy

The total potential energy  $\Pi$  of the foundation-soil system, including both internal and external potential energies, is given by.

$$\Pi = U_{foundation} + U_{soil} - U_{external} \quad (3.6)$$

where  $U_{foundation}$  = strain energy in the foundation,  $U_{soil}$  = strain energy in the soil, and  $U_{external}$  = work done by external loads.

The strain energy stored in the foundation due to the bending and torsion is obtained as follows:

$$U_{foundation} = \frac{E_p I_p}{2} \int_0^{L_p} \left( \frac{d^2 w_r}{dz^2} \right)^2 dz + \frac{G_p J_p}{2} \int_0^{L_p} \left( \frac{d^2 \psi_p}{dz^2} \right)^2 dz \quad (3.7)$$

where  $I_p$  = moment of inertia of the foundation cross section ( $= \pi r_p^4/4$ ) and  $J_p$  = polar moment of inertia of foundation cross section ( $= \pi r_p^4/2$ ). Similarly, the strain energy in the soil is obtained by integrating the strain energy density of the soil ( $= \frac{1}{2} \sigma_{pq} \varepsilon_{pq}$  where  $\sigma_{pq}$  and  $\varepsilon_{pq}$  are the stress and strain tensors in the soil, respectively) over the soil volume as follows:

$$\begin{aligned} U_{soil} = & \frac{1}{2} \int_0^\infty \int_{r_p}^\infty \int_0^{2\pi} \left[ (\lambda_s + 2G_s) \left( w_r \frac{d\phi_r}{dr} \cos \theta \right)^2 + (\lambda_s + 2G_s) \left\{ \frac{w_r \cos \theta}{r} (\phi_\theta - \phi_r) \right\}^2 \right. \\ & - 2\lambda_s w_r^2 \frac{d\phi_r}{dr} \left( \frac{\phi_\theta - \phi_r}{r} \right) \cos^2 \theta + G_s \left\{ w_r \frac{\phi_r}{r} \sin \theta + (w_r \sin \theta - r_p \psi_p) \left( \frac{d\phi_\theta}{dr} - \frac{\phi_\theta}{r} \right) \right\}^2 \\ & + G_s \left( \frac{dw_r}{dz} \phi_r \cos \theta \right)^2 + G_s \left\{ \left( \frac{dw_r}{dz} \sin \theta - r_p \frac{d\psi_p}{dz} \right) \phi_\theta \right\}^2 \left. \right] rd\theta dr dz \\ & + \frac{1}{2} \int_{L_p}^\infty \int_0^{r_p} \int_0^{2\pi} \left[ G_s \left( \frac{r_p \psi_p}{r} \right)^2 + G_s \left( \frac{dw_r}{dz} \cos \theta \right)^2 + G_s \left( \frac{dw_r}{dz} \sin \theta - r_p \frac{d\psi_p}{dz} \right)^2 \right] rd\theta dr dz \end{aligned} \quad (3.8)$$

For the multilayered system as shown in Figure 3.1, Eq. (3.8) can be rewritten with properties of each soil layer:

$$\begin{aligned}
U_{soil} = & \sum_{i=1}^N \frac{\pi}{2} \int_{z_{H,i-1}}^{z_{H,i}} \int_{r_p}^{\infty} \left[ (\lambda_{si} + 2G_{si}) w_{ri}^2 \left( \frac{d\phi_r}{dr} \right)^2 + (\lambda_{si} + 2G_{si}) w_{ri}^2 \left( \frac{\phi_\theta - \phi_r}{r} \right)^2 \right. \\
& - 2\lambda_{si} w_{ri}^2 \frac{d\phi_r}{dr} \left( \frac{\phi_\theta - \phi_r}{r} \right) + G_{si} \left( \frac{w_{ri} \phi_r}{r} \right)^2 + G_{si} w_{ri}^2 \left( \frac{d\phi_\theta}{dr} - \frac{\phi_\theta}{r} \right)^2 + 2r_p^2 G_{si} \psi_{pi}^2 \left( \frac{d\phi_\theta}{dr} - \frac{\phi_\theta}{r} \right)^2 \\
& \left. + 2G_{si} w_{ri}^2 \frac{\phi_r}{r} \left( \frac{d\phi_\theta}{dr} - \frac{\phi_\theta}{r} \right) + G_{si} \left( \frac{dw_{ri}}{dz} \right)^2 (\phi_r^2 + \phi_\theta^2) + 2G_{si} r_p^2 \left( \frac{d\psi_{pi}}{dz} \right)^2 \phi_\theta^2 \right] r dr dz \\
& + \sum_{i=m+1}^N \frac{\pi}{2} \int_{z_{H,i-1}}^{z_{H,i}} \int_0^{r_p} \left[ 2G_{si} \left( \frac{r_p \psi_{pi}}{r} \right)^2 + 2G_{si} \left( \frac{dw_{ri}}{dz} \right)^2 + 2G_{si} r_p^2 \left( \frac{d\psi_{pi}}{dz} \right)^2 \right] r dr dz
\end{aligned} \tag{3.9}$$

where  $w_{ri}$  and  $\psi_{pi}$  are the functions  $w_r(z)$  and  $\psi_p(z)$  within the  $i^{\text{th}}$  layer.

The work done by external loads is given by:

$$U_{external} = H w_r \Big|_{z=0} + T \psi_p \Big|_{z=0} \tag{3.10}$$

### 3.2.5 Principle of minimum potential energy

The principle of minimum potential energy states that a conservative system attains its equilibrium formation when its total potential energy is at a minimum (i.e. setting the first variation of the potential energy  $\delta\Pi$  equal to zero, where  $\delta$  is a variational operator).

Applying  $\delta\Pi = 0$  to Eq. (3.6) yields many terms that contain the first variations  $\delta w_r$ ,  $\delta\phi_r$ ,  $\delta\psi_p$ , and  $\delta\phi_\theta$ , and we obtain the following form of the equation by collecting and rearranging the terms:

$$A(w_r) \delta w_r + B(\phi_r) \delta\phi_r + C(\psi_p) \delta\psi_p + D(\phi_\theta) \delta\phi_\theta = 0 \tag{3.11}$$

Because the functions  $w_r$ ,  $\phi_r$ ,  $\psi_p$ , and  $\phi_\theta$  in Eq. (3.11) are not known *a priori*, their variations are not zero according to the variational principle. Furthermore, since these functions are independent one another, Eq. (3.11) is satisfied if and only if their coefficients  $A(w_r)$ ,  $B(\phi_r)$ ,  $C(\psi_p)$ , and  $D(\phi_\theta)$  are all zero. The equilibrium configuration of the foundation-soil system is obtained when these expressions [ $A(w_r) = 0$ ,  $B(\phi_r) = 0$ ,  $C(\psi_p) = 0$ , and  $D(\phi_\theta) = 0$ ] are solved, which represent the governing differential equations of the functions  $w_r(z)$ ,  $\phi_r(r)$ ,  $\psi_p(z)$ , and  $\phi_\theta(r)$ .

### 3.2.6 Governing differential equation for lateral displacement function $w_r$

The governing differential equation for the lateral displacement function  $w_{ri}(z)$  in any layer  $i$  is obtained by equating the coefficients of  $\delta w_{ri}$  to zero. Two sub-domains are considered for the function  $w_{ri}(z)$ : within the foundation length ( $0 \leq z \leq L_p$ ) and beneath the foundation ( $L_p < z < \infty$ ).

For the domain within the foundation length ( $0 \leq z \leq L_p$ ), the governing differential equation for the function  $w_{ri}(z)$  is given as

$$E_p I_p \frac{d^4 w_{ri}}{dz^4} - 2t_{ri} \frac{d^2 w_{ri}}{dz^2} + k_{ri} w_{ri} = 0 \quad (3.12)$$

and, the differential equation for the domain beneath the foundation ( $L_p < z < \infty$ ) is given as

$$-2t_{ri} \frac{d^2 w_{ri}}{dz^2} + k_{ri} w_{ri} = 0 \quad (3.13)$$

where

$$t_{ri} = \begin{cases} \frac{\pi G_{si}}{2} \int_{r_p}^{\infty} (\phi_r^2 + \phi_\theta^2) r dr; & i = 1, 2, \dots, m \\ \frac{\pi G_{si}}{2} \left[ \int_{r_p}^{\infty} (\phi_r^2 + \phi_\theta^2) r dr + r_p^2 \right]; & i = m+1, \dots, N \end{cases} \quad (3.14)$$

$$\begin{aligned}
k_{ri} = \pi \left[ \right. & (\lambda_{si} + 2G_{si}) \int_{r_p}^{\infty} \left( \frac{d\phi_r}{dr} \right)^2 r dr + G_{si} \int_{r_p}^{\infty} \left( \frac{d\phi_{\theta}}{dr} \right)^2 r dr + 2\lambda_{si} \int_{r_p}^{\infty} (\phi_r - \phi_{\theta}) \frac{d\phi_r}{dr} dr \\
& \left. + 2G_{si} \int_{r_p}^{\infty} (\phi_r - \phi_{\theta}) \frac{d\phi_{\theta}}{dr} dr + (\lambda_{si} + 3G_{si}) \int_{r_p}^{\infty} \frac{1}{r} (\phi_r - \phi_{\theta})^2 dr \right]; \quad i = 1, 2, \dots, N
\end{aligned} \tag{3.15}$$

Note that the index  $i$  for the domain within the foundation length ( $0 \leq z \leq L_p$ ) ranges from 1 to  $m$  and, for the domain beneath the foundation base it ranges from  $m+1$  to  $N$  (see Figure 3.1). Because Eq. (3.12) is 4<sup>th</sup> order differential equation and there are  $m$  layers within the foundation, a total of  $4m$  boundary conditions are needed to solve Eq. (3.12). First, four boundary conditions are obtained at the foundation head and base as follows:

$$E_p I_p \frac{d^3 w_{r1}(0)}{dz^3} - 2t_{r1} \frac{dw_{r1}(0)}{dz} = H \tag{3.16}$$

(shear force at foundation head = applied lateral load)

$$E_p I_p \frac{d^2 w_{r1}(0)}{dz^2} = 0 \quad (\text{bending moment at foundation head} = 0) \tag{3.17}$$

$$E_p I_p \frac{d^3 w_{rm}(L_p)}{dz^3} - 2t_{rm} \frac{dw_{rm}(L_p)}{dz} = -2t_{r(m+1)} \frac{dw_{r(m+1)}(L_p)}{dz} \tag{3.18}$$

(continuity of shear force at foundation base)

$$E_p I_p \frac{d^2 w_{rm}(L_p)}{dz^2} = 0 \quad (\text{bending moment at foundation base} = 0) \tag{3.19}$$

The remaining boundary conditions are then obtained from the continuity of variables at the interfaces within the foundation. These conditions yield  $4m - 4$  equations as follows because we have  $m-1$  interfaces ( $i=1, 2, \dots, m-1$ ):

$$w_{r_i}(z_{H,i}) = w_{r_{(i+1)}}(z_{H,i}) \text{ (continuity of foundation displacement)} \quad (3.20)$$

$$\frac{dw_{r_i}(z_{H,i})}{dz} = \frac{dw_{r_{(i+1)}}(z_{H,i})}{dz} \text{ (continuity of slope of foundation displacement)} \quad (3.21)$$

$$E_p I_p \frac{d^2 w_{r_i}(z_{H,i})}{dz^2} = E_p I_p \frac{d^2 w_{r_{(i+1)}}(z_{H,i})}{dz^2} \text{ (continuity of foundation bending moment)} \quad (3.22)$$

$$E_p I_p \frac{d^3 w_{r_i}(z_{H,i})}{dz^3} - 2t_{r_i} \frac{dw_{r_i}(z_{H,i})}{dz} = E_p I_p \frac{d^3 w_{r_{(i+1)}}(z_{H,i})}{dz^3} - 2t_{r_{(i+1)}} \frac{dw_{r_{(i+1)}}(z_{H,i})}{dz} \text{ (continuity of shear force in foundation)} \quad (3.23)$$

Similarly, Eq. (3.13) is 2<sup>nd</sup> order differential equation and there are  $N - m$  layers beneath the foundation base; therefore, a total of  $2(N - m)$  boundary conditions are needed to solve Eq. (3.13). Two boundary conditions are obtained at the foundation base and infinite depth as follows:

$$w_{r_m}(L_p) = w_{r_{(m+1)}}(L_p) \text{ (displacement continuity at foundation base)} \quad (3.24)$$

$$w_{r_N}(\infty) = 0 \text{ (zero displacement at infinite depth)} \quad (3.25)$$

The remaining  $2(N - m) - 2$  boundary conditions are obtained from the continuity of variables at the interfaces between the two neighboring soil layers beneath the foundation base ( $i = m+1, \dots, N-1$ ) as follows:

$$w_{r_i}(z_{H,i}) = w_{r_{(i+1)}}(z_{H,i}) \text{ (continuity of soil displacement)} \quad (3.26)$$

$$2t_{r_i} \frac{dw_{r_i}(z_{H,i})}{dz} = 2t_{r_{(i+1)}} \frac{dw_{r_{(i+1)}}(z_{H,i})}{dz} \text{ (continuity of shear force in soil)} \quad (3.27)$$

### 3.2.7 Governing differential equation for angle of twist function $\psi_p$

The governing differential equation for the angle of twist function  $\psi_{pi}(z)$  in any layer  $i$  is obtained by equating the coefficients of  $\delta\psi_{pi}$  to zero. Two sub-domains exist for the function  $\psi_{pi}(z)$ : within the foundation length ( $0 \leq z \leq L_p$ ) and beneath the foundation ( $L_p < z < \infty$ ).

For the domain within the foundation length ( $0 \leq z \leq L_p$ ), the governing differential equation for the function  $\psi_{pi}(z)$  is given as

$$-(G_p J_p + 2t_{\theta i}) \frac{d^2 \psi_{pi}}{dz^2} + k_{\theta i} \psi_{pi} = 0 \quad (3.28)$$

and, the differential equation for the domain beneath the foundation ( $L_p < z < \infty$ ) is given as

$$-2t_{\theta i} \frac{d^2 \psi_{pi}}{dz^2} + k_{\theta i} \psi_{pi} = 0 \quad (3.29)$$

where

$$t_{\theta i} = \begin{cases} \pi r_p^2 G_{si} \int_{r_p}^{\infty} \phi_{\theta}^2 r dr; & i = 1, 2, \dots, m \\ \pi r_p^2 G_{si} \left( \frac{r_p^2}{2} + \int_{r_p}^{\infty} \phi_{\theta}^2 r dr \right); & i = m+1, \dots, N \end{cases} \quad (3.30)$$

$$k_{\theta i} = \begin{cases} 2\pi r_p^2 G_{si} \int_{r_p}^{\infty} \left( \frac{d\phi_{\theta}}{dr} - \frac{\phi_{\theta}}{r} \right)^2 r dr; & i = 1, 2, \dots, m \\ 2\pi r_p^2 G_{si} \left[ \ln(r_p) - \lim_{\varepsilon \rightarrow 0} \{\ln(\varepsilon)\} + \int_{r_p}^{\infty} \left( \frac{d\phi_{\theta}}{dr} - \frac{\phi_{\theta}}{r} \right)^2 r dr \right]; & i = m+1, \dots, N \end{cases} \quad (3.31)$$

Note that in Eq. (3.31)  $k_{\theta i}$  beneath the foundation base is not defined at  $r = 0$  because  $\ln(0)$  is undefined. To avoid such a numerical issue, the lower limit of integration was changed from  $r = 0$  to  $r = \varepsilon$  where  $\varepsilon$  is taken as a sufficiently small positive number ( $\varepsilon = 0.001$  m is used in this study).

Because Eq. (3.28) is 2<sup>nd</sup> order differential equation and there are  $m$  layers within the foundation, a total of  $2m$  boundary conditions are needed to solve Eq. (3.28). First, two boundary conditions are obtained at the foundation head and base as follows:

$$-(G_p J_p + 2t_{\theta 1}) \frac{d\psi_{p1}(0)}{dz} = T \quad (\text{torque at foundation head} = \text{applied torque}) \quad (3.32)$$

$$-(G_p J_p + 2t_{\theta m}) \frac{d\psi_{pm}(L_p)}{dz} = -2t_{\theta(m+1)} \frac{d\psi_{p(m+1)}(L_p)}{dz} \quad (3.33)$$

(continuity of torque at foundation base)

The remaining  $2m - 2$  boundary conditions are then obtained from the continuity requirements at the interfaces within the foundation ( $i = 1, 2, \dots, m-1$ ) as follows:

$$\psi_{pi}(z_{H,i}) = \psi_{p(i+1)}(z_{H,i}) \quad (\text{continuity of angle of twist of foundation}) \quad (3.34)$$

$$-(G_p J_p + 2t_{\theta i}) \frac{d\psi_{pi}(z_{H,i})}{dz} = (G_p J_p + 2t_{\theta(i+1)}) \frac{d\psi_{p(i+1)}(z_{H,i})}{dz} \quad (3.35)$$

(continuity of torque in foundation)

Similarly, a total of  $2(N - m)$  boundary conditions are needed to solve Eq. (3.29). Two boundary conditions are obtained at the foundation base and infinite depth as follows:

$$\psi_{pm}(L_p) = \psi_{p(m+1)}(L_p) \quad (\text{continuity of angle of twist at foundation base}) \quad (3.36)$$

$$\psi_{pN}(\infty) = 0 \text{ (zero angle of twist at infinite depth)} \quad (3.37)$$

The remaining  $2(N - m) - 2$  boundary conditions are obtained from the continuity requirements at the interfaces between the two neighboring soil layers beneath the foundation base ( $i = m+1, \dots, N-1$ ) as follows:

$$\psi_{pi}(z_{H,i}) = \psi_{p(i+1)}(z_{H,i}) \text{ (continuity of angle of twist of soil column)} \quad (3.38)$$

$$-2t_{\theta i} \frac{d\psi_{pi}(z_{H,i})}{dz} = -2t_{\theta(i+1)} \frac{d\psi_{p(i+1)}(z_{H,i})}{dz} \text{ (continuity of torque in soil column)} \quad (3.39)$$

### 3.2.8 Governing differential equation for lateral displacement decay function $\phi_r$ in soil

The governing differential equation for the lateral displacement decay function  $\phi_r(r)$  in the soil is obtained by equating the coefficients of  $\delta\phi_r$  to zero and given as

$$\frac{d^2\phi_r}{dr^2} + \frac{1}{r} \frac{d\phi_r}{dr} - \left[ \left( \frac{\gamma_{rs1}}{r} \right)^2 + \left( \frac{\gamma_{rs2}}{r_p} \right)^2 \right] \phi_r = - \left( \frac{\gamma_{rs1}}{r} \right)^2 \phi_\theta + \frac{\gamma_{rs3}^2}{r} \frac{d\phi_\theta}{dr} \quad (3.40)$$

where

$$\gamma_{rs1} = \sqrt{\frac{\sum_{i=1}^N (\lambda_{si} + 3G_{si}) \int_{z_{H,i-1}}^{z_{H,i}} w_{ri}^2 dz}{\sum_{i=1}^N (\lambda_{si} + 2G_{si}) \int_{z_{H,i-1}}^{z_{H,i}} w_{ri}^2 dz}} \quad (3.41)$$

$$\gamma_{rs2} = r_p \sqrt{\frac{\sum_{i=1}^N G_{si} \int_{z_{H,i-1}}^{z_{H,i}} \left( \frac{dw_{ri}}{dz} \right)^2 dz}{\sum_{i=1}^N (\lambda_{si} + 2G_{si}) \int_{z_{H,i-1}}^{z_{H,i}} w_{ri}^2 dz}} \quad (3.42)$$

$$\gamma_{rs3} = \sqrt{\frac{\sum_{i=1}^N G_{si} \int_{z_{H,i-1}}^{z_{H,i}} w_{ri}^2 dz + \sum_{i=1}^N \lambda_{si} \int_{z_{H,i-1}}^{z_{H,i}} w_{ri}^2 dz}{\sum_{i=1}^N (\lambda_{si} + 2G_{si}) \int_{z_{H,i-1}}^{z_{H,i}} w_{ri}^2 dz}} \quad (3.43)$$

Boundary conditions for Eq. (3.40) are  $\phi(r_p) = 1$  and  $\phi(\infty) = 0$ .

3.2.9 Governing differential equation for lateral displacement decay function  $\phi_\theta$  in soil

The governing differential equation for the tangential displacement decay function  $\phi_\theta(r)$  in the soil is obtained by equating the coefficients of  $\delta\phi_\theta$  to zero and given as

$$\frac{d^2\phi_\theta}{dr^2} + \frac{1}{r} \frac{d\phi_\theta}{dr} - \left[ \left( \frac{\gamma_{\theta s1}}{r} \right)^2 + \left( \frac{\gamma_{\theta s2}}{r_p} \right)^2 \right] \phi_\theta = - \left( \frac{\gamma_{\theta s3}}{r} \right)^2 \phi_r - \frac{\gamma_{\theta s4}^2}{r} \frac{d\phi_r}{dr} \quad (3.44)$$

where

$$\gamma_{\theta s1} = \sqrt{\frac{\sum_{i=1}^N (\lambda_{si} + 3G_{si}) \int_{z_{H,i-1}}^{z_{H,i}} w_{ri}^2 dz + \sum_{i=1}^N 2\pi r_p G_{si} \int_{z_{H,i-1}}^{z_{H,i}} \psi_{pi}^2 dz}{\sum_{i=1}^N G_{si} \int_{z_{H,i-1}}^{z_{H,i}} w_{ri}^2 dz + \sum_{i=1}^N 2\pi r_p G_{si} \int_{z_{H,i-1}}^{z_{H,i}} \psi_{pi}^2 dz}} \quad (3.45)$$

$$\gamma_{\theta s2} = r_p \sqrt{\frac{\sum_{i=1}^N G_{si} \int_{z_{H,i-1}}^{z_{H,i}} \left( \frac{dw_{ri}}{dz} \right)^2 dz + \sum_{i=1}^N 2\pi r_p^2 G_{si} \int_{z_{H,i-1}}^{z_{H,i}} \left( \frac{d\psi_{pi}}{dz} \right)^2 dz}{\sum_{i=1}^N G_{si} \int_{z_{H,i-1}}^{z_{H,i}} w_{ri}^2 dz + \sum_{i=1}^N 2\pi r_p G_{si} \int_{z_{H,i-1}}^{z_{H,i}} \psi_{pi}^2 dz}} \quad (3.46)$$

$$\gamma_{\theta s3} = \sqrt{\frac{\sum_{i=1}^N (\lambda_{si} + 3G_{si}) \int_{z_{H,i-1}}^{z_{H,i}} w_{ri}^2 dz}{\sum_{i=1}^N G_{si} \int_{z_{H,i-1}}^{z_{H,i}} w_{ri}^2 dz + \sum_{i=1}^N 2\pi r_p G_{si} \int_{z_{H,i-1}}^{z_{H,i}} \psi_{pi}^2 dz}} \quad (3.47)$$

$$\gamma_{\theta s4} = \sqrt{\frac{\sum_{i=1}^N (\lambda_{si} + G_{si}) \int_{z_{H,i-1}}^{z_{H,i}} w_{ri}^2 dz}{\sum_{i=1}^N G_{si} \int_{z_{H,i-1}}^{z_{H,i}} w_{ri}^2 dz + \sum_{i=1}^N 2\pi r_p G_{si} \int_{z_{H,i-1}}^{z_{H,i}} \psi_{pi}^2 dz}} \quad (3.48)$$

Boundary conditions for Eq. (3.44) are  $\phi_{\theta}(r_p) = 1$  and  $\phi_{\theta}(\infty) = 0$ . Note that Eqs. (3.40) and (3.44) contain both  $\phi_r$  and  $\phi_{\theta}$ , suggesting that these functions are interdependent. A total of six differential equations represent the entire foundation-soil system under combined lateral and torsional loads, and they are summarized in Figure 3.2.

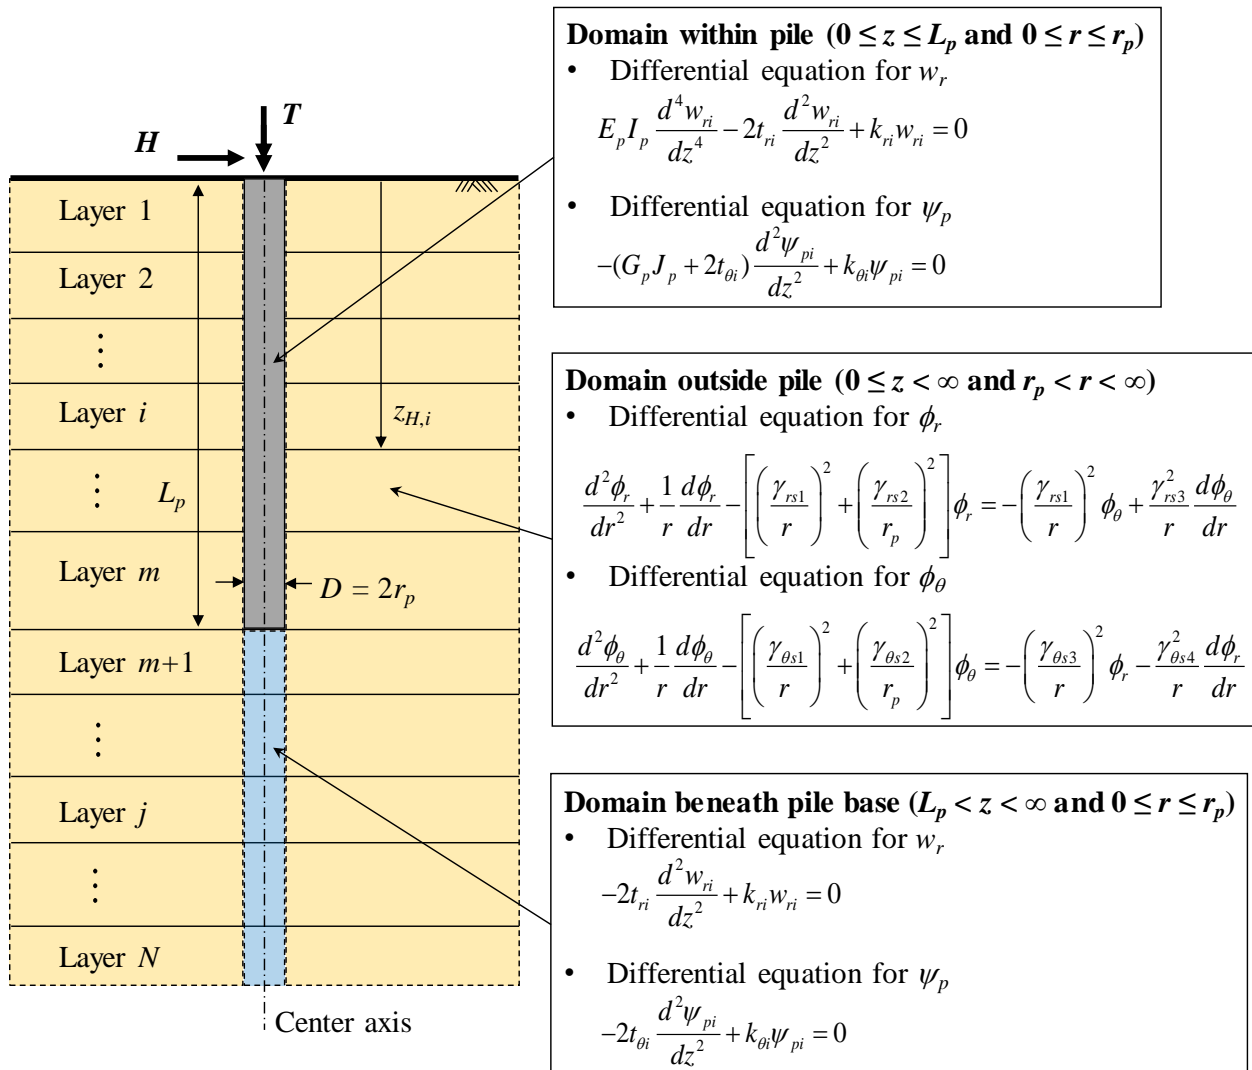

Figure 3.2 Differential equations in each sub-domain

### 3.2.10 Iterative solution scheme

Lateral displacement  $w_r$  and angle of twist  $\psi_p$  of the foundation and the soil column beneath the foundation are obtained by solving Eqs. (3.12), (3.13), (3.28), and (3.29) numerically using the finite difference method. To solve them, the soil resistance parameters  $t_{ri}$ ,  $k_{ri}$ ,  $t_{\theta i}$  and  $k_{\theta i}$  must be known, and these  $t$  and  $k$  parameters are functions of  $\phi_r$  and  $\phi_\theta$ , as seen in Eqs. (3.14), (3.15), (3.30). However, to obtain  $\phi_r$  and  $\phi_\theta$  by solving Eqs. (3.40) and (3.44), the parameters  $\gamma_{rs}$  and  $\gamma_{\theta s}$  must be known *a priori*, but

they in turn depend on  $w_r$  and  $\psi_p$  [refer to Eqs. (3.40) through (3.48)]. Due to the interdependence of the soil and foundation differential equations, an iterative solution scheme is required in our analytical model.

The iterative solution scheme employed in this study begin by assuming initial values of  $\gamma_{rs}$  parameters ( $\gamma_{rs1}^{old}$ ,  $\gamma_{rs2}^{old}$  and  $\gamma_{rs3}^{old}$ ) and  $\gamma_{\theta s}$  parameters ( $\gamma_{\theta s1}^{old}$ ,  $\gamma_{\theta s2}^{old}$ ,  $\gamma_{\theta s3}^{old}$  and  $\gamma_{\theta s4}^{old}$ ). Furthermore, due to interdependence of  $\phi_r$  and  $\phi_\theta$ , we assume initial values of  $\phi_\theta$  that satisfies the boundary conditions [*i.e.*,  $\phi_\theta(r_p) = 1$  and  $\phi_\theta(\infty) = 0$ ]. With the assumed  $\gamma_{rs}$  parameters and  $\phi_\theta$ , the function  $\phi_r$  is obtained by solving Eq. (3.40). Then, using the obtained  $\phi_r$  and assumed  $\gamma_{\theta s}$  parameters, new values of function  $\phi_\theta$  is calculated by solving Eq. (3.44). Because we now have solution to  $\phi_r$  and  $\phi_\theta$ , the soil resistance parameters  $t_{ri}$ ,  $k_{ri}$ ,  $t_{\theta i}$  and  $k_{\theta i}$  are then calculated via numerical integration. With the soil resistance parameters  $t_{ri}$ ,  $k_{ri}$ ,  $t_{\theta i}$  and  $k_{\theta i}$  known,  $w_r$  and  $\psi_p$  are obtained by solving Eqs. (3.12), (3.13), (3.28), and (3.29). Then, new values of  $\gamma_{rs}$  parameters ( $\gamma_{rs1}^{new}$ ,  $\gamma_{rs2}^{new}$  and  $\gamma_{rs3}^{new}$ ) and  $\gamma_{\theta s}$  parameters ( $\gamma_{\theta s1}^{new}$ ,  $\gamma_{\theta s2}^{new}$ ,  $\gamma_{\theta s3}^{new}$  and  $\gamma_{\theta s4}^{new}$ ) are calculated using the computed values of  $w_r$  and  $\psi_p$  and compared against the assumed initial values. If the differences are greater than the prescribed tolerance (a value of  $10^{-5}$  was used in this study), iterations are continued with the calculated values of  $\gamma_{rs}$  and  $\gamma_{\theta s}$  parameters taken as the new guess ( $\gamma_{rs}^{old} = \gamma_{rs}^{new}$  and  $\gamma_{\theta s}^{old} = \gamma_{\theta s}^{new}$ ) until the differences between old and new  $\gamma$  parameters from two successive iterations fall below the prescribed tolerance for all  $\gamma$  parameters. The iterative solution scheme is provided in the form of a flow chart in Figure 3.3.

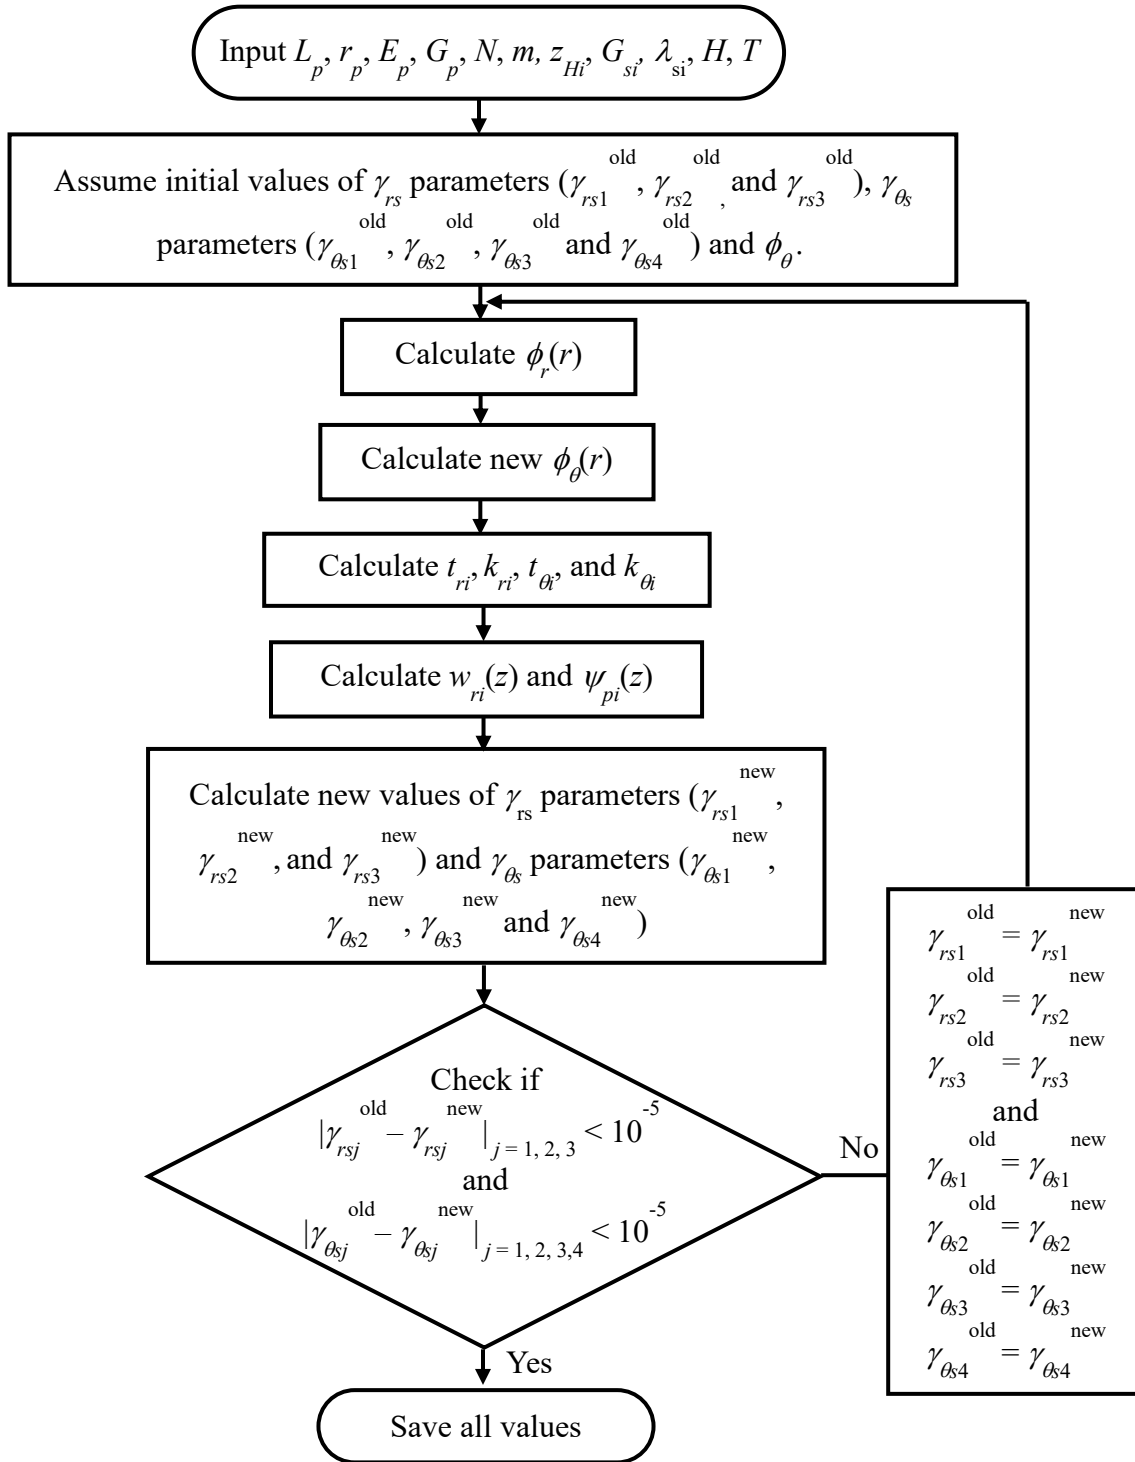

Figure 3.3 Flow chart for iterative solution scheme

### 3.3 Results and validations

Due to the absence of any previous analytical studies for a foundation under simultaneous loading of a lateral load and a torque, the validations are done for pure torsion and pure lateral load cases.

#### 3.3.1 Lateral analysis

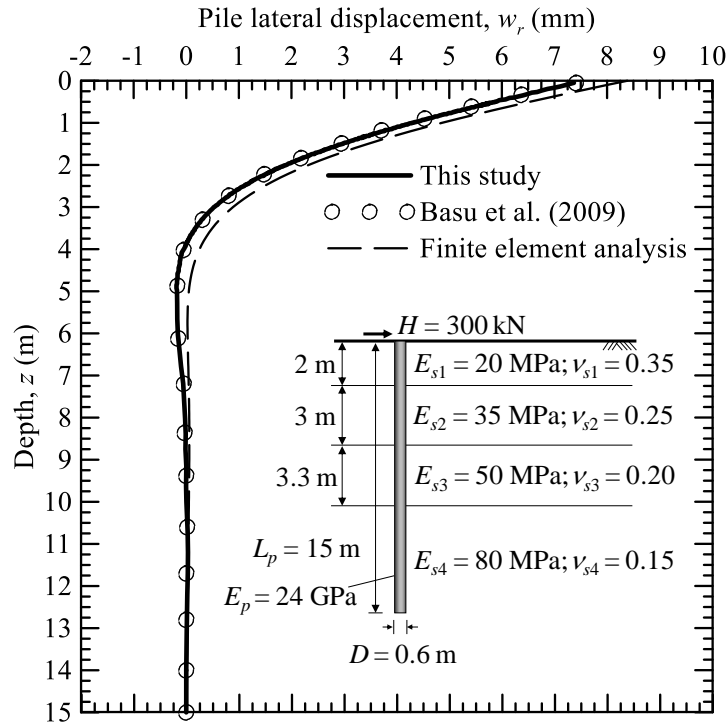

Basu et al. (2009) developed semi-analytical solutions for laterally loaded foundations in multilayered elastic soil using the variational principles and method of initial parameters. Our analysis model are derived from the same variational principles but with the displacement field resulted from *both* lateral deflection  $w_r$  and angle of twist  $\psi_p$ . Consequently, as seen in Eqs. (3.45) through (3.48), the  $\gamma$  factors associated with  $\phi_\theta$  become functions of both  $w_r$  and  $\psi_p$ . However, with the absence of the angle of twist  $\psi_p$ , the differential equations for  $w_r$ ,  $\phi_r$ , and  $\phi_\theta$  obtained from our study are simplified to the same differential equations derived in Basu et al.'s study. Therefore, when zero torque is applied in our analysis, the results from our study are expected to be the same as those from Basu et al.'s study. To verify this, we compare results from our analysis under zero torque against those from Basu et al.'s study for two example cases reported in their paper.

The first example considers a drilled shaft, 0.6 m in diameter and 15 m long, with Young's modulus  $E_p = 24$  GPa, embedded in a four-layered soil profile. Properties of the four soil layers are as follows:  $E_{s1} = 20$  MPa,  $\nu_{s1} = 0.35$ , and  $z_{H,1} = 2$  m for Layer 1;  $E_{s2} = 35$  MPa,  $\nu_{s2} = 0.25$ , and  $z_{H,2} = 5$  m for Layer 2;  $E_{s3} = 50$  MPa,  $\nu_{s3} = 0.20$ , and  $z_{H,3} = 8.3$  m for Layer 3; and  $E_{s4} = 80$  MPa and  $\nu_{s4} = 0.15$  for Layer 4 (Layer 4 extends from the bottom of the third layer to great depth). The applied lateral load  $H$  at the foundation head is 300 kN with zero torque (*i.e.*,  $T = 0$ ).

The second example considers a drilled shaft, 1.7 m in diameter and 40 m long, with Young's modulus  $E_p = 25$  GPa, embedded in a four-layered soil profile. The top three layers are located over 0-1.5 m, 1.5-5 m, and 5-13.5 m below the ground surface. The fourth layer extends from the bottom of the third layer to great depth. The elastic

constants of the four layers are as follows:  $E_{s1} = 20$  MPa and  $\nu_{s1} = 0.35$  for Layer 1,  $E_{s2} = 25$  MPa and  $\nu_{s2} = 0.30$  for Layer 2,  $E_{s3} = 40$  MPa and  $\nu_{s3} = 0.25$  for Layer 3, and  $E_{s4} = 80$  MPa and  $\nu_{s4} = 0.20$  for Layer 4. A lateral load of  $H = 3000$  kN is applied at the foundation head with zero torque.

Profiles of lateral displacement along the shaft obtained from our analysis and the study by Basu et al. (2009) for the two examples are presented in Figure 3.4. As expected, they show excellent agreements for both examples. For the first example with  $D = 0.6$  m and  $L_p = 15$  m, we performed finite element analysis using ABAQUS for comparison purpose. Although our analysis yields slightly stiffer response than FEA (perhaps due to the assumption of zero vertical soil displacement made in our analysis), it is much more efficient than FEA, in addition to being faster, in terms of pre- and post-processing of the data due to its analytical nature.

(a)

(b)

Figure 3.4 Comparison with previous studies for a foundation subjected to a pure lateral load: (a)  $D = 0.6 \text{ m}$  and  $L_p = 15 \text{ m}$  and (b)  $D = 1.7 \text{ m}$  and  $L_p = 40 \text{ m}$

### 3.3.2 Torsional analysis

Misra et al. (2014) developed closed-form solutions of the angle of twist and torque for a foundation in multilayered elastic soil subjected to a pure torque using the method of initial parameters. We compare results from our analysis against those from Misra et al.'s solution for two example cases they reported.

The first example considers a drilled shaft, 1.5 m in diameter and 10 m long ( $L_p/D = 6.7$ ), with shear modulus  $G_p = 9.6$  GPa (equivalent to  $E_p = 25$  GPa and  $\nu_p = 0.3$ ), embedded in a two-layered soil profile. The first layer extends from ground surface to a depth of 5 m with the elastic constants  $E_{s1} = 25$  MPa and  $\nu_{s1} = 0.40$ , and the second layer extends to great depth with  $E_{s2} = 100$  MPa and  $\nu_{s2} = 0.20$ . The applied torque  $T$  at the foundation head is 100 kN-m with zero lateral load (*i.e.*,  $H = 0$ ).

The second example considers a drilled shaft, 1.0 m in diameter and 30 m long ( $L_p/D = 30$ ), embedded in a four-layered soil profile. The top three layers are located over 0-5 m, 5-10 m, and 10-20 m below the ground surface. The fourth layer extends from the bottom of the third layer to great depth. The elastic constants of the four layers are as follows:  $E_{s1} = 25$  MPa and  $\nu_{s1} = 0.45$  for Layer 1,  $E_{s2} = 50$  MPa and  $\nu_{s2} = 0.35$  for Layer 2,  $E_{s3} = 75$  MPa and  $\nu_{s3} = 0.30$  for Layer 3, and  $E_{s4} = 100$  MPa and  $\nu_{s4} = 0.25$  for Layer 4. The shear modulus  $G_p$  is 9.6 GPa, and torque  $T = 100$  kN-m is applied at the foundation head with zero lateral load.

The angles of twist  $\psi_p$  versus depth  $z$  obtained from our analysis and the study by Misra et al. (2014) for the two examples are presented in Figure 3.5, and they show excellent agreement (note that  $\psi_p$  beneath the foundation base was not reported in Misra et al.'s study and hence not presented in Figure 3.5). Both examples suggest that the angle of twist decreases with increasing depth because more soils resist to the applied torque as the depth increases. Due to its high embedment depth ratio of  $L_p/D = 30$  for the foundation in the four-layered soil deposit, an angle of twist becomes zero at the foundation base (see Figure 3.5b). However, the foundation with  $L_p/D = 6.7$  in the two-layered deposit show more rigid behavior than the foundation with  $L_p/D = 30$ , leading to

a non-zero value of angle of twist at the foundation base; but  $\psi_p$  quickly diminishes through the soil beneath the foundation base (see Figure 3.5a).

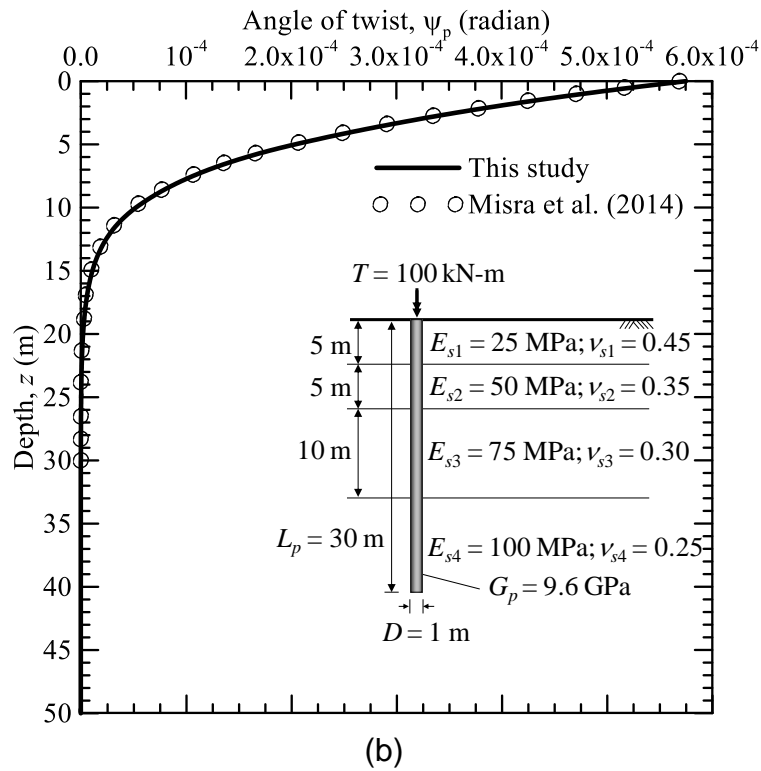

Figure 3.5 Comparison with previous studies for a foundation subjected to a pure torsion: (a) two-layered deposit and (b) four-layered deposit

### 3.4 Future studies

The new analysis model developed in this chapter is valid for linear elastic soils only. Furthermore, the short duration of the project prohibited a full implementation of solution algorithm under the combined loading. However, given that our analysis model shows very good agreement with previous studies and FEA under individual loading components, the solution algorithm developed in this study can be fully implemented and thorough benchmark runs can be performed as future studies. Furthermore, this study can be regarded as the groundwork for more advanced analyses such as nonlinear analysis that considers degradation of soil modulus using a piecewise-linear approach. Also, because the new analysis model is applicable for a multilayered soil, a systematic parametric study can be performed to investigate the soil layering effect and optimize foundation design.

## CHAPTER 4. SUMMARY AND CONCLUSIONS

In this study, we performed a nonlinear finite element analysis (FEA) for a circular foundation in a homogeneous clay under combined loading of a lateral load and a torque using Tresca model. Failure envelopes in a lateral-torsional loading plane were obtained from FEA, and the effect of a torsional load on the lateral capacity of a circular foundation was quantified as a function of torque-to-lateral load ratio. We further developed a novel, linear-elastic analysis model for a circular foundation, embedded in a multilayered soil, under concurrent application of lateral and torsion loads using energy principles and variational calculus.

To determine collapse loads, the displacement-controlled swipe loading path method was employed in FEA. As a validation of the finite element model, the results from FEA under each individual component of load were compared against previous studies and theoretical values, which showed an excellent agreement. Analysis results under combined loading were presented in the form of failure envelopes with various embedment depth ratios ( $L_p/D$ ) using four definitions of ultimate lateral capacity. For foundations with embedment depth ratios less than 3, the normalized failure envelopes fell on top of each other regardless of how lateral ultimate capacity was defined, suggesting that a single failure envelope can be used for short foundations. However, as the embedment depth ratio increased, the normalized failure envelopes deviated from each other and the use of single failure envelope was not justified for  $L_p/D = 10$ .

Results from FEA clearly showed that lateral capacity was reduced by the concurrent application of torsion. Such reduction effects were quantified as a function of torque-to-lateral load ratio and presented in the form of design charts. Analysis results further indicated that the lateral capacity could be reduced to 63% of maximum value under a torque-to-lateral load ratio of about 0.58 for the soil condition and the range of torque-to-lateral load ratio ( $T/H$ ) considered in this study. Whether the lateral capacity will continue to decrease beyond the range of  $T/H$  considered in this study is unknown at

this time and warrants further investigation. Typical ranges of  $T/H$  for various transportation infrastructures will need to be examined in future studies as well.

We also derived governing differential equations for a circular foundation, embedded in a layered soil, subjected to a combination of torsional and lateral loads based on energy principles and variational calculus. For the foundation-soil system under concurrent application of lateral and torsional loads, a total of six interdependent differential equations were obtained. We further developed a numerical algorithm to solve the interdependent differential equations using an iterative scheme and tested the algorithm under individual loading components. The results from our analysis model under individual loading components showed very good agreements with those from previous studies and FEA.

The solution algorithm developed in this study can be fully implemented for combined loading case and thorough benchmark runs can be performed as future studies. Furthermore, the analysis model developed in this study can be regarded as the groundwork for more advanced models such as nonlinear analysis model that considers degradation of soil modulus using a piecewise-linear approach. Also, because the new analysis model is applicable for a multilayered soil, a systematic parametric study can be performed to investigate the soil layering effect and optimize foundation design.
